## 1.0 Introduction

A pre-design investigation at the PSC Metals Vicinity Property (DT-8) was conducted by Shaw Environmental, Inc. (Shaw) for the U.S. Army Corps of Engineers (USACE), St. Louis District, from 1999 through 2005. The pre-design investigation activities were conducted in accordance with the Formerly Utilized Sites Remedial Action Program (FUSRAP). The FUSRAP was developed in 1974 by the Atomic Energy Commission (AEC; now the U.S. Department of Energy [DOE]) to identify and clean up or otherwise control sites where residual radioactive contamination remained from activities carried out under contract to the Manhattan Engineer District (MED) and the AEC during the early years of the nation's atomic energy program (Bechtel National, Inc. [BNI], 1994). Subsequently, Congress transferred responsibility for the FUSRAP to the USACE.

The *Record of Decision for the St. Louis Downtown Site, St. Louis Missouri* (ROD) (USACE, 1998) identified the St. Louis Downtown Site (SLDS) as requiring remediation of chemical and radiological contamination. Radiological contamination was defined by the ROD as the presence of radiological contaminants of concern (COCs) in soil at concentrations exceeding the ROD criteria. In the context of this pre-design investigation report, radiological contamination is defined as the presence of COCs in an individual soil sample or group of samples at net concentrations (above the background concentration) that exceed ROD remediation criteria.

However, the presence of COCs at concentrations that exceed ROD remediation criteria in an individual sample or group of samples may not exceed ROD remedial goals (RGs). The determination of whether residual radiological activity is less than RGs is beyond the scope of this report and will be made based on the results of additional sampling performed in accordance with the *Final Status Survey Plan for Accessible Soil Within Mallinckrodt Property and the Vicinity Properties, Excluding Plants 1, 2 and the City Property at the St. Louis Downtown Site, St. Louis, Missouri* (FSSP) (USACE, 2002). If RGs are exceeded, the area will be excavated.

Note that the background concentration used in this pre-design investigation report is defined by the arithmetic mean of the distribution of background measurements that have been collected at the SLDS. As identified by the ROD, the radiological COCs at the SLDS are uranium-238 (U-238) and its daughters, especially thorium-230 (Th-230) and radium-226 (Ra-226); U-235 and its decay products, including protactinium-231 (Pa-231) and actinium-227 (Ac-227); and thorium-232 (Th-232) and its progeny.

The SLDS consists of the Mallinckrodt Inc. (Mallinckrodt) plant (a chemical manufacturer) and surrounding vicinity properties, one of which is the DT-8 (USACE, 1998). During characterization and remedial investigation activities conducted by BNI at the SLDS between 1986 and 1990, radiological contamination was identified at a number of soil sample locations on the McKinley Iron property (later identified as PSC Metals property), and that property was included as a vicinity property identified in the ROD (USACE, 1998) requiring remediation. In this report, the original McKinley Iron/PSC Metals property tract will be referred to as the "South Tract." Subsequent to the BNI investigations, a better understanding of the property boundaries, contaminant distribution, and changes to the property ownership over the years has been obtained. The USACE updated the DT-8 vicinity property descriptions in 2002 to include other property holdings or operations of PSC Metals in the immediate area of the original South Tract property and the Mallinckrodt Plant.

As currently defined by the USACE for the purpose of the FUSRAP SLDS project, the DT-8 is composed of seven separate land tracts as illustrated on Figure 1. Within those general boundaries, there are land tracts not owned by PSC Metals that are not considered part of the DT-8. Several small areas of contamination located on surrounding properties that are contiguous to contamination associated with the PSC Metals property are addressed by this report.

UNCONTROLLED

In order to prepare for the remedial design and remediation of the DT-8, the USACE authorized a pre-design investigation be conducted at the DT-8. The purpose of the pre-design investigation at DT-8 was to further identify and define the estimated extent of contamination of the land tracts and to characterize the physical conditions of the land tracts for remedial design. The pre-design investigation activities conducted at the DT-8, and the results obtained during these activities, are described in this pre-design investigation report, which supersedes the previous *Pre-Design Investigation Data Summary Report, PSC Metals Vicinity Property (DT-8), FUSRAP St. Louis Downtown Site, St. Louis, Missouri*, Revision 0 (IT Corporation [IT], 2001a) in its entirety. This Revision 1 (this document) incorporates the information contained in the 2001 report as well as the methods, activities, and results of the subsequent investigations. Data and information from the *Remedial Investigation Report for the St. Louis Downtown Site, St. Louis, Missouri* (Remedial Investigation Report) (BNI, 1994); the *Remedial Investigation Addendum for the St. Louis Site, St. Louis, Missouri* (Remedial Investigation Addendum) (Science Applications International Corporation [SAIC], 1995); and the *Radiological, Chemical, and Hydrogeological Characterization Report for the St. Louis Downtown Site in St. Louis, Missouri* (Characterization Report) (BNI, 1990) were also used in this report. The analytical results for selected soil

4  
samples collected as part of historical sampling or pre-design investigation activities at properties adjacent to the DT-8 were used to develop an understanding of subsurface conditions on surrounding properties and whether similar subsurface conditions may exist on the DT-8. These analytical results were presented in reports issued for those specific properties, are available in the SLDS project files, and have not been included in this report.

UNCONTROLLED

## 2.0 Pre-Design Investigation Activities and Methods

As noted in Section 1.0, the development of the currently recognized DT-8 property boundaries and land tracts to be included in the investigation occurred in several steps based on information available at the time. Similarly, the scope of work for the pre-design investigation was developed in phases.

The initial scope of work was presented in the *Pre-Design Investigation Work Description, Phillip Metals Vicinity Property, FUSRAP St. Louis Downtown Site, St. Louis, Missouri*, Revision 0 (IT, 2000a) (Work Description). That Work Description described the following investigation activities to be conducted at the (now designated) South Tract:

- Performing a gamma radiological walkover survey
- Identifying potential Class 1, 2, and 3 Survey Units
- Completing up to 20 planned delineation borings around previously identified areas of radiological activity exceeding ROD remediation criteria
- Providing 42 potential Class 2 Survey Unit samples and up to 24 planned potential Class 3 Survey Unit samples to document the absence of contamination exceeding ROD remediation criteria in other areas of the South Tract
- Collecting and analyzing one or more composite waste characterization samples

The field work for that initial scope of work was largely completed by October 2000, and a report of the findings and results (*Pre-Design Investigation Data Summary Report, PSC Metals Vicinity Property [DT-8], FUSRAP St. Louis Downtown Site, St. Louis, Missouri*) (IT, 2001a) was developed and issued in May 2001 as Appendix A.3.1 of the *Small Area Remediation Work Area-Specific Description, FUSRAP St. Louis Downtown Site, St. Louis, Missouri* (IT, 2001b). As part of the 1999 Plant 6 East Half pre-design investigation, some samples were collected on the DT-8 property. These sample locations have been included in this report. Note that the *Pre-Design Investigation Data Summary Report* (Revision 0) for DT-8 indicated that samples were collected and analyzed from a total of 19 near-surface borings, 42 potential Class 2 and 23 potential Class 3 borings, and 1 waste characterization sample.

The USACE authorized a historical background review be conducted at the DT-8 to determine if residual contamination may have been inadvertently buried, relocated, or removed through normal property development or modifications over time, subsequent to initial deposition. A number of areas or features of interest that warranted further investigation were identified during the historical background review. In April 2002, the USACE authorized a second phase of

investigation to be conducted at the South Tract to evaluate whether subsurface contamination or targets of interest were present on the DT-8. This phase of investigation included borings, soil sampling, and analysis at seven specific locations and additional radiological surveys with contingent sampling at eight other areas of interest where previously collected radiological data suggested additional investigation was warranted. The scope of work for the second phase of investigation may be found in Field Work Variance 104 to the Work Description (IT, 2000a).

A third phase of investigation was authorized for the DT-8 by the USACE in September 2002 via Field Work Variance 110 to the *Pre-Design Investigation Work Description, Vicinity Properties, St. Louis Downtown Site, St. Louis, Missouri*, Revision 1 (Work Description) (IT, 2001c). In this phase of investigation, the north and east property tracts were added to the property description and investigation, additional gamma radiological walkover surveys were authorized, and up to 35 pre-design investigation borings, along with soil sampling and analytical work, and up to 82 potential Class 2 borings with soil sampling and analytical work were proposed. Contingency borings, samples, and analytical work were also included in the scope of work. Field Work Variance 112 to the Work Description (IT, 2001c) further modified the third phase of the investigation to provide an additional ten sample locations associated with (previous) gamma radiological walkover surveys, seven sample locations associated with a (previous) characterization gamma radiological walkover survey, and two samples associated with building gutter debris. The third phase of investigation was again modified in May 2005 with the addition of six sample locations along with contingency sample locations and delineation sampling for the north and south property tracts to provide further delineation of the radiological conditions and characterization of the subsurface conditions encountered during the earlier sampling efforts (Appendix B.2, *2005 Additional Pre-Design Investigation at the PSC Metals Vicinity Properties, of the Pre-Design Investigation Work Description, FUSRAP St. Louis Downtown Site, St. Louis Missouri* [Shaw, 2004]).

Pre-design investigation activities were conducted under the guidance and direction received from the USACE throughout the investigation. Pre-design investigation methods are summarized in the following subsections. Details of the methods used can be found in the previously referenced Work Descriptions, on boring logs (see Appendix A) and other field documentation, and in analytical data tables.

## **2.1 Historical Information Review Methods**

A review of available historical information sources and documents was performed as part of the pre-design investigation to gain insights as to when land development activities and/or related

physical changes occurred at the DT-8 and surrounding properties. These land development activities/changes included the placement of fill material, earth movement activities that may have altered the topography, and the addition, removal, or modification of man-made structural elements. Historical drainage/erosional features were also identified. The land development activities and the locations of the drainage/erosional features were then compared with the known MED/AEC operational activities or site characteristics and their associated timeframes to identify areas of the DT-8 that may have been affected by MED/AEC operations.

Specific consideration was given to the identification of the historical topographic surface at the DT-8 and surrounding areas at the time of the MED/AEC operations. This historical topographic surface likely consisted of fill material that overlies the alluvial deposits referred to as the "natural, in situ soil horizon." This natural, in situ soil horizon served as a marker horizon because its homogeneity across the SLDS made it easily identifiable during subsurface investigations. The natural, in situ soil horizon also provided a reference horizon that indicated that the subsurface investigation was below the topographic surface that would have been present during and after Mallinckrodt's MED/AEC operational activities. The historical topographic surface was suspected to be present at approximately 420 feet (+/- 5 feet) above mean sea level (msl) at other SLDS locations where radiological contamination has been identified. Therefore, the historical information review included an evaluation of the natural, in situ soil horizon at the DT-8 and the potential for radiological contamination conditions similar to those identified at other SLDS locations (including preferential pathways for contaminant migration) to be present at the DT-8.

Radiological and geological data from the remedial investigation, pre-design investigations at the DT-8 and surrounding vicinity properties, and remediation activities at nearby Mallinckrodt plants and vicinity properties were also utilized to develop insights into the nature and extent of the soil units at the DT-8. The potential for these soil units to contain radiological contamination was then estimated. Historical information sources and documents included the following:

- Historical sampling results, including results for those samples obtained during characterization and remedial investigations activities at the SLDS (BNI, 1990, 1994 and SAIC, 1995)
- Historical analytical results from previous sampling at Mallinckrodt Plant 1 (IT, 1999a), the City of Venice, Illinois Vicinity Property (DT-11) (IT, 2001b [see Appendix A.5.1]), the MSD Liftstation Vicinity Property (DT-15) (USACE, 2001a), and the City Property Vicinity Property (DT-2) (USACE, 1999)
- Sanborn Maps® (The Sanborn Map Company Inc., 1909, 1950, 1989, 1990, 1992, 1993, 1994, and 1995)

- Historical topographic maps (United States Geological Survey [USGS], 1933, 1935, 1937, 1940, 1950, 1954, 1968, and 1993)
- Eighty-six aerial photographs covering approximately 36 dates provided by the USACE, Geospatial Engineering Branch (USACE, 2001b) and other aerial photographs compiled by Shaw throughout the investigation

Additionally, a field reconnaissance was performed as part of the historical information review. Field reconnaissance activities consisted of a visual assessment and documentation of the following:

- Surface features that may affect field operations (e.g., structures, utilities, or debris that may preclude sample collection in a particular area); and
- Topographic characteristics such as evidence of disturbed ground, depressed areas, runoff/erosional areas, etc.

## **2.2 Gamma Walkover Surveys and Sampling Methods**

A gamma radiological walkover survey was conducted by SAIC in accordance with the *Multi-Agency Radiation Survey and Site Investigation Manual* (MARSSIM) (U.S. Nuclear Regulatory Commission [USNRC] et al., 1997) requirements to identify areas of elevated radiological activity within the uppermost layer of soil at the DT-8. The gamma radiological walkover survey was conducted in accessible areas of the DT-8 utilizing a 2-inch by 2-inch (2 x 2) sodium iodide detector. Five soil samples were collected in conjunction with the gamma radiological walkover survey from areas exhibiting an elevated radiological count rate.

Subsequent to the initial pre-design investigation, gamma radiological walkover surveys were conducted to confirm previously identified areas of elevated radioactivity count rates and to better define the boundaries of areas exhibiting elevated radiological count rates. Soil samples were also collected in conjunction with these gamma radiological surveys to identify areas containing radiological COCs. The gamma radiological surveys were conducted in accordance with instructions and specifications provided in the previously described Work Descriptions or at the direction of the USACE.

Soil samples collected and analyzed in conjunction with the gamma radiological surveys were collected in accordance with the Work Descriptions and submitted to the St. Louis FUSRAP Laboratory under chain-of-custody for analyses by gamma spectroscopy for SLDS radiological COCs. Results from the gamma radiological surveys and soil sampling are presented and discussed in Sections 3.0 and 4.0 of this report.

### 2.3 Soil Sampling Methods

In accordance with the authorized Work Descriptions, sampling locations were identified using standard surveying methods, and the locations were then marked with paint, flags, or stakes. Prior to collecting soil samples, all sampling tools were decontaminated in accordance with the *Sampling and Analysis Guide for the St. Louis Sites, St. Louis, Missouri* (SAG) (USACE, 2000). Decontamination residuals were containerized and ultimately disposed in accordance with the *Materials Handling and Transportation Plan, FUSRAP St. Louis Downtown Site, St. Louis, Missouri* (IT, 1999b).

Most pre-design investigation borings were drilled using a Diedrich D-120 or a Central Mine Equipment 55 or 75 drill rig equipped with 4.25-inch or 3.25-inch inside diameter hollow stem augers (see specific boring logs in Appendix A for actual method used for a specific boring). Soil samples for evaluation of radiological activity were collected using a 2-foot-long by 3-inch outside diameter (OD) steel split spoon sampling device. Soil samples for evaluation of geotechnical characteristics were collected using a 2-foot-long by 2-inch OD steel split spoon sampling device. The split spoon was driven in advance of the hollow stem auger using a 140-pound automatic drop hammer activated over a 30-inch drop height (or equivalent). After each 2-foot evaluation length was collected, the augers were advanced 2 feet to the bottom of the previous evaluation length and the procedure repeated until boring/sampling completion.

Where conditions would not allow the use of a drill rig (e.g., due to the presence of overhead power lines, proximity of structures), soil borings/samples were completed using a 0.5-foot-long by 4-inch OD steel hand auger. Extensions for the hand auger shaft allowed for the collection of soil samples to a depth of 6 feet below ground surface (bgs). Soil borings/samples drilled using a hand auger were advanced at 0.5-foot increments with a pre-cleaned or decontaminated steel sample bucket. The sample bucket was carefully lowered to the bottom of the borehole to prevent scraping and dislodging of sidewall material from the borehole. The depth of penetration of the auger was closely monitored to ensure that the retrieved soil sample was representative of the appropriate sample interval.

The soil cores were field screened for radiological activity using a Ludlum Model 2221 (scaler/ratemeter) together with a Ludlum Model 44-10 (2 x 2 sodium iodide detector). During drilling activities, soil was also screened for volatile organic compounds (VOCs) using a photoionization or flame ionization detector. The field geologist identified and lithologically described the soils using American Society for Testing and Materials (ASTM) Method D2488-93, *Standard Practice for Description and Identification of Soils (Visual-Manual*

*Procedure*) (ASTM, 1993). The lithologic information and the screening results were recorded on the soil boring log at the time of boring advancement. If applicable during logging, particular attention was paid to identifying the existence of remnant surface soil horizons, erosional zones, or other historical indicators (e.g., debris zones).

At various locations, a test pit or trench was used (instead of a soil boring) to allow for characterization of the subsurface by direct observation as well as to allow for collection of subsurface samples due to access restrictions or sampling difficulties encountered at the planned sampling location. A backhoe was typically used to excavate the test pit. Test pit activities (e.g., excavating, sampling, stockpiling, and backfilling) were conducted in accordance with authorized Work Description.

Soil samples from the appropriate 0.5-foot interval were collected and processed in accordance with the SAG (USACE, 2000) or a specific Work Description, placed in 1-quart containers with tight-fitting lids, submitted to the St. Louis FUSRAP Laboratory under chain-of-custody, and analyzed by gamma spectroscopy for SLDS COCs. Soil samples collected for archiving were placed in double-bagged plastic bags with sealable openings. The samples were then transported to the on-site storage trailer under chain-of-custody in accordance with SAG procedures. Results from the soil sampling are presented and discussed in Sections 3.0 and 4.0 of this report.

Upon completion of drilling and sampling, each boring was backfilled in accordance with the SAG or as directed by the USACE. Subsequent to backfilling the soil borings or test pits, each location was either civil surveyed or its distance measured from a known point (nearby surveyed feature). Coordinate location data are retained in the project files.

## **2.4 Waste Characterization Sampling and Investigation-Derived Waste**

One five-part composite waste characterization sample (SLD06650) was collected within the DT-8 to evaluate waste acceptance criteria for disposal purposes. A discrete sample (SLD06650-4) was collected for the VOC component portion of the waste characterization sample using the procedure described below. Each of the soil sub-samples collected was screened for VOCs using a photoionization detector in addition to radiological screening. The discrete soil sample for VOC analysis was collected from the interval that exhibited the maximum photoionization reading from the five sub-samples.

The soil-composite sample for waste characterization evaluation was submitted to Severn Trent Services Laboratory for the following analyses: toxicity characteristic leaching procedure (TCLP) pesticides, TCLP herbicides, TCLP metals (eight Resource Conservation and Recovery

Act metals plus copper and zinc), polychlorinated biphenyls, total organic halides, corrosivity, ignitability, reactivity, and the paint-filter test. The discrete sample collected for VOC analysis was submitted for TCLP VOC analysis.

Investigation-derived waste generated during the pre-design investigation activities included personal protective equipment, soil cores or cuttings, disposable sampling equipment, decontamination fluids, and plastic sheeting. This material was placed at the SLDS load-out facility, loaded into railcars, and transported off site to an approved disposal facility.

## **2.5 Interpretive Methods**

Soil samples (SLD-series or HTZ-series samples) were submitted to the St. Louis FUSRAP Laboratory and analyzed for radiological COCs by gamma spectroscopy. The gamma spectroscopy results were used to evaluate radiological conditions and help determine the estimated extent of radiological contamination. Alpha spectroscopy analysis was also performed for Th-230 and Th-232 on a portion of the soil samples. For those samples also analyzed by alpha spectroscopy, those results for Th-230 and Th-232 were used as the input for interpretation of the pre-design investigation results. Samples with PSC-series designations were considered screening level samples and, as such, were not subject to the same level of analysis, reporting, or quality assurance/quality control as samples initially designated for contaminant determination purposes (typically SLD-series and HTZ-series samples). In certain instances, selected PSC-series samples were subsequently selected for reanalysis using the SAG-prescribed methods and reassigned a SLD-series designation. In the event that reanalysis was completed for a PSC-series sample, the reanalyzed results (with the better quality data) were reported and used in this report. In the event that a PSC-series sample was not reanalyzed, the initial screening data were reported and used in this report.

The radiological soil sample results for each sample were imported into a working database to calculate the sum-of-ratios net ( $SOR_{net}$ ) value for each sample. If the detection limit for an analyte exceeded the result, then one-half of the detection limit value was used for calculating the  $SOR_{net}$  value in accordance with U.S. Environmental Protection Agency (USEPA) guidance (USEPA, 2000). The background values were subtracted from the gross radionuclide results prior to calculating the  $SOR_{net}$  value. The equations used to calculate the  $SOR_{net}$  values are as follows:

Samples from 0 to 0.5 feet bgs (the ground surface begins at the topographic surface):

$$SOR_{net} = \frac{\text{Greater of Ra-226 or Th-230}}{5 \text{ pCi/g}} + \frac{\text{Greater of Ra-228 or Th-232}}{5 \text{ pCi/g}} + \frac{U-238}{50 \text{ pCi/g}}$$

Where pCi/g = picocuries per gram

Samples greater than 0.5 feet bgs:

$$SOR_{net} = \frac{\text{Greater of Ra-226 or Th-230}}{15 \text{ pCi/g}} + \frac{\text{Greater of Ra-228 or Th-232}}{15 \text{ pCi/g}} + \frac{U-238}{50 \text{ pCi/g}}$$

After calculation of the  $SOR_{net}$ , the  $SOR_{net}$  and analytical results for each sample were compared to the ROD remediation criteria (USACE, 1998) to determine if radiological contamination was present. A sample with a  $SOR_{net}$  greater than or equal to 1.0 was assumed to be contaminated. If contamination was identified, the available data and information were evaluated further to estimate the horizontal extent of radiological contamination. The term "contamination," as defined in Section 1.0 and used herein, differs from the RG usage in that the RGs are based on the average concentration of SLDS COCs within the entire population of data that are above the site background distribution for a 100-square-meter area.

When radiological contamination was detected within a sample from a particular sample interval (e.g., from 0 to 0.5 feet bgs), it was conservatively assumed for volume and cost estimation purposes that the depth of the contamination at that location extended to the top of the next sampled interval that did not contain radiological COCs. Based on the foregoing evaluation, potential remediation areas and/or contamination contours were identified to aid in estimating the soil volume to be removed to achieve the RGs identified in the ROD. The estimated extent of contamination was then presented in a series of figures. If the area represented by the estimated extent of contamination coincided with historical or geological features of interest identified during the historical review, the outline of the feature(s) of interest was also portrayed on the estimated-extent-of-contamination map. Areas in which one or more samples exhibit an  $SOR_{net}$  exceeding 1.0 but which may not exceed ROD (USACE, 1998) RGs, when evaluated in accordance with the FSSP (USACE, 2002), are marked with shading on the estimated-extent-of-contamination maps as described in Section 4.0 to identify them for further evaluation during the design phase. Since the estimated-extent-of-contamination contours illustrated in this report do not reflect the required excavation contours, the gross excavation contours will be provided in the DT-8 remedial design.

### **3.0 Pre-Design Investigation Results**

Pre-design investigation results include the historical information findings, soil sample analytical results, and geology and hydrogeology information from the DT-8. The boring logs are included in Appendix A.

#### **3.1 Historical Information Findings**

As a result of the historical review, a number of historical, structural, and geological features have been identified within the various DT-8 property tracts (Figures 2-A through D). These features and their association with the DT-8 were evaluated to determine their potential impact to the properties with regard to contaminant existence, migration, or concentration. A summary of the historical information and findings, documentation records for the historical background review, owner/operator interviews, and site reconnaissance is located in the SLDS project files. Discussions were organized to generally present or compare the historical information related to the MED/AEC era (1940s – 1950s). The historical perspectives were used in conjunction with the analytical data and other characterization data to assist with the interpretation of contaminant boundaries.

#### **3.2 Gamma Radiological Walkover Survey Results**

Gamma radiological walkover survey results were compiled from each of the investigations and are presented in Appendix B. As a result of identifying elevated readings during the survey, 86 biased samples designated by the HTZ prefix were collected from 49 locations, and 39 screening samples designated by the PSC or MIP prefix were collected from 23 locations. Forty-one of the 86 HTZ samples and five of 39 PSC or MIP samples showed contamination, with depths of contamination ranging from ground surface at numerous locations to at least 2.0 feet bgs at sample location HTZ66213.

#### **3.3 Pre-Design Investigation Analytical Results**

Eight hundred eight soil samples from 319 sample locations were collected from the seven property tracts composing the DT-8 and analyzed for SLDS radiological COCs. Figures 3-A through D depict the sample locations. Table C-1 in Appendix C lists the analytical results from the samples collected and analyzed from the pre-design investigation conducted at the DT-8. Subsequent discussions in this report will use data rounded to two significant figures. As a result, data discussed within the text may not exactly reflect the data as reported in the tables or in actual laboratory reports. Seventy-one samples (including HTZ, MIP, SLD, and PSC series) exhibited an  $SOR_{net}$  of 1.0 or greater (see Table 3-1). The highest  $SOR_{net}$  value (790) was

identified at sample HTZ69418, collected from 0 to 0.5 feet bgs. HTZ69418 was reported to contain 2,300 pCi/g of Ra-228 and Th-232; 1,700 pCi/g of Th-230; 50 pCi/g of U-238; and 4.0 pCi/g of Ra-226. The deepest estimated extent of contamination (6 feet bgs) was based on elevated radium concentrations noted at sample location SLD04160 (sample SLD04268) at a depth of 4.5 to 5.0 feet bgs. The  $SOR_{net}$  values associated with samples exhibiting an  $SOR_{net}$  of 1.0 or more are shown on Figures 4-A through D and the results are listed on Table 3-1.

Waste characterization analytical methods, parameters, and results are presented in Table 3-2. The complete laboratory analytical report is presented as Appendix D. The locations of the five sub-samples collected for waste characterization are also shown on Figure 3-C.

### **3.4 Geology and Hydrogeology**

The geological setting at the SLDS is characterized from surface to bedrock by a fill layer present over most of the site, and alluvial sediments located beneath the fill (USACE, 1998). The fill, discernable as multiple horizons at some locations, has an average thickness of 13 feet and may contain concrete, brick, glass, coal cinders, slag material, and/or other miscellaneous material. Along the eastern boundary of the SLDS near the Mississippi River, fill as thick as 30 feet or more was placed on top of the original floodplain sediments as the SLDS area was developed during the late 1800s and early 1900s. Fill thickness along the western boundary of the SLDS is generally 10 to 15 feet (USACE, 1998). The alluvial deposits underlying the fill consist of stratified clays, silts, sands, and gravels, and range in thickness from 5 to 30 feet.

Ground water at the SLDS has been identified within three hydrostratigraphic units (HUs): HU-A, HU-B, and HU-C. HU-A comprises the fill material and the upper portion of the underlying alluvial deposits. HU-B, also called the Mississippi Alluvial Aquifer, comprises the lower portions of the alluvial deposits and consists of sands and silty sands. HU-C is located within the limestone bedrock. Ground water in the St. Louis area is generally of poor quality and does not meet drinking water standards without treatment (USACE, 1998).

The seven property tracts composing the DT-8 are sufficiently large to cover the range of geological and hydrogeological conditions as previously described for the SLDS project area. At property tracts closer to the western side of the project, fill sequences tend to be thinner and the natural, in situ soil horizon is typically closer to the surface. At property tracts closer to the eastern side of the project area, fill sequences are thicker and the natural, in situ soil horizon is much deeper. Topographic relief across the DT-8 tracts can be variable depending upon the fill sequences and urbanization of the area. In the 1930s, topographic relief in the western portions of the DT-8 (North Tract 1) consisted of a gentle slope (0.008 feet per foot) traversing the river

embankment and entering the floodplain (which was essentially flat at 420 feet above msl). All of the other property tracts were situated within a depression (410 – 420 feet above msl) located within the floodplain. North Tract 3, North Tract 4, South Tract, and the eastern one-half of North Tract 2 were located on the slopes of the depression with slopes averaging 0.16 feet per foot. The western one-half of North Tract 2 appears to be well situated within the base of the depression (at approximately 410 feet above msl). The DT-8 pre-design investigation was targeted primarily within HU-A. When encountered, ground water in the upper fill layers of that unit tended to be isolated and perched. The primary ground water was typically encountered within the upper several feet of the natural, in situ soil layer. Specific information pertaining to the geology and hydrogeology of the various tracts can be obtained from the boring logs (see Appendix A).

### **3.5 Quality Assurance/Quality Control**

Throughout the pre-design investigation conducted at the DT-8, various quality assurance and quality control methods were used to develop an understanding of the quality and usefulness of the investigative methods used, data obtained, and interpretations made. A precision, accuracy, representativeness, completeness, and comparability (PARCC) parameter analyses was performed for the laboratory analytical data by the SAIC Data Management Group. In general summary, the laboratory data were determined to be within control limits and useable for their intended purpose with respect to precision, accuracy, and representativeness. The percent completeness for the sampling effort was reported at 99.9 percent. It was also reported that the current and historical information are sufficiently comparable to allow a reasonable determination of the nature and extent of the radiological contamination. The complete PARCC parameter report is provided in Appendix E.

On many of the land tracts, new fill units or replacement fill units appeared to have been placed within the designated estimated contaminated area or surrounding areas. As a result, the contaminated layer may have been covered, removed, or replaced. Some analytical data from the recent fill units suggested that they were at or below background radioactivity levels. Other sample data from these units suggested that while they were elevated above background radioactivity levels, radioactivity levels were not sufficiently high to be considered contaminated. Thus, some fluctuation in the estimated extent of contamination boundaries should be expected.

## 4.0 Evaluation of Pre-Design Investigation Results

In this section, the analytical results for each land tract associated with the DT-8 property are evaluated in conjunction with the relevant geological and historical data and the gamma radiological walkover survey data. Sample locations with  $SOR_{net}$  values equal to or greater than 1.0, and the estimated horizontal and vertical extent of contamination, are highlighted on Figures 4-A through D. Table 3-1 lists sample data with  $SOR_{net}$  values greater than or equal to 1.0, and the gamma radiological walkover survey results are provided in Appendix B.

### 4.1 Property Conditions – North Tract 1

Five areas of radiological contamination (labeled 1 through 5 on Figure 4-A) were identified on the North Tract 1 at the DT-8. The locations of the radiologically contaminated areas and their associated depths of radiological contamination are identified on Figure 4-A. Table C-1 lists the analytical results, and Table 3-1 lists the analytical results resulting in  $SOR_{net}$  values equal to or greater than 1.0.

Other significant property conditions identified through the historical background review or encountered during the field investigation activities and associated with North Tract 1 include the following:

- Elevated gamma radiological walkover survey results indicated potential contamination associated with soils surrounding the building located in the south central portion of the property. Two samples (SLD76942 and SLD76943) were taken of debris lodged in a rain gutter located along the top of the north wall of the south central building surrounding Area 3 to evaluate whether the elevated gamma radiological walkover survey results were caused by precipitation runoff from the building. Both samples were collected from the same location approximately 2 feet east of the northwest corner of the building. One sample was collected from approximately 0.3 feet below the top of the gutter while the second sample was collected from approximately 0.6 feet below the top of the gutter. Both samples contained  $SOR_{net}$  values below 1.0 (0.9 and 0.7 respectively); however, both contained radioactivity above background levels. The scope of work included plans to collect another set of samples from the gutter located on the northern wall, closer to the eastern side of the building; however, prior to attempting to collect those samples, the gutter fell away from the building and samples could not be recovered.
- During the pre-design investigation, utility locating was performed to clear sample locations for intrusive subsurface work. A number of underground utilities were identified (e.g., gas lines) approaching or entering the North Tract 1 property along the western side of the property and situated to connect to the vacant buildings remaining on the property. Overhead utilities were noted entering the western side

of the property and also along the northern side of the property across Bremen Street. Any further work considered in this area should avoid damaging the utilities. As on other SLDS properties, buried utility conduits can serve as preferential pathways.

- During the pre-design investigation, the building foundations, associated utilities, or other building features were not identified, explored, or mapped. However, these features should be anticipated in the area.

#### 4.1.1 Area 1

Area 1 (see Figure 4-A) is situated along the northern boundary of the North Tract 1 near the northwestern corner of the property. Area 1 covers approximately 10,752 square feet (999 square meters) and extends from approximately 60 feet east of the west property fence to approximately 240 feet east of the west property fence and from the north property fence southward approximately 100 feet. Analytical data indicate that the radiological contamination extends beyond the northern border immediately adjacent to Bremen Street as indicated on Figure 4-A. The estimated radiologically contaminated area was defined based on the gamma radiological walkover survey and analytical data associated with five soil sample locations (HTZ66254, HTZ66219, HTZ66222, HTZ66256, and HTZ66213) in which  $SOR_{net}$  values were reported equal to or greater than 1.0. The estimated extent of contamination area was developed on the basis of additional soil sample locations (SLD72939, SLD87283, SLD72144, SLD72145, SLD72146, HTZ66252, SLD72943, SLD87284, SLD87322, SLD87285, SLD72951, SLD72947, SLD72792, SLD72955, PSC00212, SLD72146, and HTZ66218), three of which (SLD72943, SLD72951, and SLD72947) contained  $SOR_{net}$  values equal to or greater than 1.0. Figure 4-A highlights the sample locations with  $SOR_{net}$  values equal to or greater than 1.0 and lists the  $SOR_{net}$  for each sample. The deepest estimated depth of contamination in Area 1 was at 3.0 feet bgs due to elevated Ra-226 in sample location SLD72939. The primary COC contributing to the radiological contamination in Area 1 was U-238. Radiological data for specific isotopes can be found in Table C-1.

Other significant property conditions identified through the historical background review or encountered during the field investigation activities and associated with Area 1 include the following:

- A number of utilities located within Bremen Street (north of the property) were identified during the historical background review. Since the extent of contamination has been interpreted to extend north of the property line and potentially into Bremen Street, contamination may have migrated to or along these lines.

- A building foundation (see Figure 2-A) was noted in/near Area 1 approximately 80 feet east of the western fence (eastern foundation wall). If further work is performed in or adjacent to Area 1, this foundation may be encountered. Further, preferential pathways and/or contaminant migration barriers may be associated with this foundation. Historical documents suggest the foundation was approximately 40 feet x 100 feet, oriented with the long side of the building in a north-south direction. The foundation was completely covered with at least 1.0 foot of fill material (mostly limestone gravel). Test pits and borings were used to explore the extent of contamination present in the subsurface, and during these intrusive activities, the north and west foundation walls were encountered. The foundation wall consisted of large blocks of limestone stacked in a wall orientation. Based on observations from test pits, no mortar was noted to have been used to construct the foundation. In several places within the test pits, piping and steel pins were noted within the rock foundation. The building foundation was not completely excavated; thus, other potential features were not identified, but may be present.

#### 4.1.2 Area 2

Area 2 (see Figure 4-A) is situated in the southwest corner of the North Tract 1. Area 2 is approximately coincident with a former rail spur, and extends from the western fence line to approximately 120 feet southeast of the west property fence and then 60 feet farther (due) east of the west property fence. It is approximately 30 feet wide throughout its extent. The former spur extended to a large, rectangular-shaped building situated near the south central part of the property. Subsequent build-out of the building appears to have positioned the spur within the building. The estimated radiologically contaminated area was identified on the basis of radiological, historical, and geological information that identified the feature and three HTZ-series samples (HTZ66217, HTZ66262, and HTZ66259), one SLD-series sample (SLD72157), and one PSC-series sample (PSC0176) that contained  $SOR_{net}$  values equal to or greater than 1.0. Additional samples surrounding Area 2 indicated that elevated radioactivity existed in some areas but was not at sufficient concentration to be considered as radiological contamination.

The extent of radiological contamination in Area 2 was estimated based on gamma radiological walkover survey results, analytical data from soil sampling, and geological and historical information pertaining to property characteristics. Radiological contamination in Area 2 was estimated to extend to approximately 2.0 feet bgs throughout the approximately 6,200-square-foot (576-square-meter) area. The primary COCs contributing to the radiological contamination noted in Area 2 were U-238, Th-230, and Ra-226.

#### **4.1.3 Area 3**

Area 3 (see Figure 4-A) is located in the south central part of the North Tract 1 inside a large, rectangular building with no floor. The currently identified radiologically contaminated area is somewhat uniformly shaped, consisting of an approximate 12-foot-radius area. The estimated radiologically contaminated area was identified during a gamma radiological walkover survey and was confirmed with HTZ70904, which had an  $SOR_{net}$  of 3.9 reported from 0 to 0.5 feet bgs. Contamination was also reported to a depth of 1.5 feet bgs ( $SOR_{net}$  of 1.0) at HTZ70904 and vertical delineation was not achieved; however, the concentration was so reduced in the second sampling interval that the contamination is not expected to extend to a significantly greater depth. One other sample location (SLD72162) was located within the general area. No samples with  $SOR_{net}$  values equal to or greater than 1.0 were reported from sample location SLD72162. The primary COC contributing to the radiological contamination in Area 3 was U-238; however, significantly high levels of Th-230 and Ra-226 were also noted in samples from that location.

Vertical delineation was not achieved at sample location HTZ70904 because no samples were collected at a depth greater than 1.5 feet bgs. However, vertical delineation of Area 3 was achieved using sample location SLD72162, located adjacent to HTZ70904, that yielded  $SOR_{net}$  values of less than 1.0 at depths greater than 1.5 feet bgs. Therefore, the extent of contamination in Area 3 was vertically and horizontally delineated adequately using the gamma radiological walkover survey data and available soil analytical results. Area 3 covers approximately 600 square feet (56 square meters). Radiological contamination was estimated to extend to at least 0.5 feet bgs throughout Area 3.

#### **4.1.4 Areas 4 and 5**

Area 4 (see Figure 4-A) is located in the southeast part of the North Tract 1 inside a large, rectangular building with a dirt floor, and Area 5 is located on the north side of this same building. Both locations appear to be isolated small areas. Radiological contamination was estimated to a shallow depth of 0.5 feet bgs in both areas. Areas 4 and 5 cover approximately 195 square feet (18 square meters) each.

#### **4.2 Property Conditions – North Tract 2**

One area of radiological contamination (Area 6) was identified on the North Tract 2 at the DT-8; other samples within North Tract 2 exhibited elevated levels of radioactivity, but not at contaminant levels. The location of the estimated contaminated area and its associated depth of radiological contamination are identified on Figure 4-B.

#### 4.2.1 Area 6

Area 6 (see Figure 4-B) is situated in the west central portion of the North Tract 2. Area 6 extends approximately 100 feet in a northwest-southeast orientation and 50 feet in a northeast-southwest orientation. The identified estimated radiologically contaminated area is irregular in shape and appears to coincide with a former drainage swale or low-lying topographic area (see Figure 2-B). The estimated radiologically contaminated area was identified from gamma radiological walkover survey data and four soil samples (HTZ69453, HTZ69451, HTZ69452, and SLD72213) that contained  $SOR_{net}$  values equal to or greater than 1.0. Vertical delineation of the HTZ sample points was not obtained. Additional samples (SLD72210, SLD72211, SLD72975, SLD72212, SLD72979, SLD72983, SLD72397, SLD72399, SLD72400, SLD72398, SLD72987, and SLD72806) surrounding and within Area 6 were used to assist with identifying the extent of contamination. Radiological contamination in Area 6 was estimated to extend to approximately 1.0 foot bgs throughout the approximately 3,700-square-foot (344-square-meter) area and is anticipated to be primarily surficial in nature. The primary COCs contributing to the estimated radiological contamination noted in Area 6 were Ra-226, Th-230, and U-238.

A number of water pipes crossing the North Tract 2 were identified during the historical background review. Since the estimated extent of radiological contamination has been interpreted to extend across at least one of these lines, these utilities may be encountered if additional work is planned for this area, and contamination may have migrated to or along these lines in the past.

#### 4.3 Property Conditions – North Tract 3

Four areas of radiological contamination (designated Areas 7 through 10) were identified on the North Tract 3 at the DT-8. Other areas within the North Tract 3 exhibit elevated levels of radioactivity, but not at contaminant levels. The locations of the radiologically contaminated areas and their associated depths of radiological contamination are identified on Figure 4-C.

Other significant property conditions identified through the historical background review or encountered during the field investigation activities and associated with North Tract 3 include the following:

- Several rail spurs were located within the property from at least the early 1940s. Those spurs continue to exist in approximately the same locations today. Local surface drainage and regional flooding associated with the Mississippi River have been associated with such features in the past. Small areas of elevated radioactivity may reside throughout the rail spur areas.

- Shallow perched ground water should be anticipated in non-continuous permeable fill or soil layers throughout the area. A more consistent ground water bearing unit should be anticipated at the natural, in situ soil unit within HU-A.

#### 4.3.1 Area 7

Area 7 (see Figure 4-C) is situated in the southwest corner of the North Tract 3. Area 7 extends approximately 180 feet in a west-east orientation from the western property line and approximately 25 feet in a north-south orientation from the southern property line. The identified radiologically contaminated area is irregular in shape. The estimated area of radiological contamination was based on the gamma radiological walkover survey data and sample analytical data from HTZ00266, HTZ69432, HTZ69417, and SLD72827 that contained  $SOR_{net}$  values equal to or greater than 1.0. While samples associated with sample location SLD72991 did not exhibit  $SOR_{net}$  values above 1.0, this location was included in the estimated radiological contamination contours because of the elevated Ra-226 levels (11.2 pCi/g) found at 3.1 to 3.6 feet bgs. Activity in samples SLD72999, SLD73003, SLD72427, HTZ69436, SLD72428, HTZ66274, and SLD72430 surrounding and within Area 7 are above background concentrations but are not at sufficient concentration to be considered as radiological contamination.

Radiological contamination was estimated to extend to approximately 0.5 feet bgs throughout the eastern portion of Area 7, but was estimated to extend to approximately 3.5 feet bgs in the western portion of Area 7. The total contaminated area associated with Area 7 was approximately 4,287 square feet (398 square meters). The primary COCs contributing to the radiological contamination noted in Area 7 were Ra-226 and Th-230.

#### 4.3.2 Area 8

Area 8 (see Figure 4-C) is situated along the northern property line in approximately the western central part of the property of the North Tract 3. Area 8 extends approximately 10 feet in diameter. Radiological contamination was estimated to extend to approximately 0.5 feet bgs throughout Area 8 (approximately 600 square feet [56 square meters]). The estimated area of radiologically contaminated soil was based on gamma radiological walkover surveys and on the basis of analytical results from HTZ66271 that contained an  $SOR_{net}$  equal to or greater than 1.0. Analytical results surrounding HTZ66271 contained  $SOR_{net}$  results less than 1.0.

#### 4.3.3 Area 9

Area 9 (see Figure 4-C) is situated in the northeastern portion of the North Tract 3. Area 9 extends approximately 60 feet in a west-east orientation and approximately 25 feet in a north-

south orientation. The estimated radiologically contaminated area is elliptical in shape and is situated between two rail spurs. The estimated area of radiologically contaminated soil was based on gamma radiological walkover surveys and analytical results from HTZ66267 and HTZ00268 that contained an  $SOR_{net}$  equal to or greater than 1.0. Activity in samples SLD73015, SLD73013, SLD06175, SLD72504, SLD73017, SLD72477, and PSC00218 surrounding and within Area 9 is elevated, but not at sufficient concentration to be considered as radiological contamination.

Radiological contamination was estimated to extend to approximately 0.5 feet bgs throughout Area 9 (approximately 1,400 square feet [130 square meters]). The primary COCs contributing to the radiological contamination noted in Area 9 were Th-230, Ra-226, and U-238.

#### **4.3.4 Area 10**

Area 10 (see Figure 4-C) is situated along the south central border of the North Tract 3 in the area of the former Salisbury Street Roadbed. Area 10 extends approximately 50 feet in a north-south orientation and approximately 25 feet in an east-west orientation. The estimated radiologically contaminated area is elliptical in shape and is situated across the North Tract 3 boundary line. The area was identified from gamma radiological walkover surveys and analytical results from HTZ69418 ( $SOR_{net} = 790$ ), HTZ00267 ( $SOR_{net} = 2.0$ ), and HTZ66280 ( $SOR_{net} = 1.0$ ).

Radiological contamination was estimated to extend to approximately 0.5 feet bgs within Area 10 (approximately 1,886 square feet [175 square meters]). The primary COC contributing to the radiological contamination was Th-230; elevated levels of Ra-226 and U-238 were also noted.

#### **4.4 Property Conditions – South Tract**

Four areas of radiological contamination are estimated to be present on the South Tract at the DT-8 and are designated as Areas 11 through 14 on Figure 4-C. Samples collected from other areas throughout the South Tract exhibited concentrations above background levels of radioactivity, but did not result in  $SOR_{net}$  values that exceeded 1.0.

Ground water can be expected in the shallow subsurface at the South Tract. Periodically, spots of perched ground water were noted during sampling (SLD04356, SLD04357, and PSC00138). A fairly consistent ground water zone was noted shortly after encountering the natural, in situ soil unit (approximately 10 feet bgs). This ground water unit may also be related to a former creek channel situated along the southern edge of the property.

#### 4.4.1 Area 11

Area 11 (see Figure 4-C) is located along the southern edge of the South Tract property, extending from Hall Street on the west to Wharf Street (Burlington Northern Santa Fe Railroad) on the east, and from the southern property line northward approximately 75 feet along an irregularly shaped path. It is known that the radiological contamination identified along the southern DT-8 property line extends southward into Mallinckrodt Plant 6 West Half and Plant 6 East Half; however, further discussion pertaining to the Plant 6 properties is not included in this report. The estimated radiologically contaminated area was defined based on gamma radiological walkover surveys and soil sample data including four HTZ-series, 13 SLD-series, 11 BNI-series, and one PSC-series samples that reported  $SOR_{net}$  values equal to or greater than 1.0. Figure 4-C highlights the sample locations with  $SOR_{net}$  values equal to or greater than 1.0 and lists the  $SOR_{net}$  for each associated sample. The analytical data for the samples collected at these locations is provided in Table C-1. The boring logs for the pre-design investigation sample locations are contained in Appendix A.

Area 11 covers approximately 30,684 square feet (2,851 square meters). Radiological contamination was estimated to extend to at least 0.5 feet bgs throughout most of Area 11 and to 6 feet bgs in an area on the east side of Area 11. In some areas, (e.g., SLDS load out area), additional cover material may have been added (or may continue to be added) to the area after the pre-design investigation samples were collected. Other significant property conditions identified on the South Tract through the historical background review or encountered during the field investigation activities include the following:

- Elevated levels (14 pCi/g) of Th-230 were noted at SLD70102 at a depth of 9.3 to 9.8 feet bgs. Additional evaluation of the subsurface at depth was authorized by the USACE in 2005. These samples indicated no significant levels of Th-230 at 7.5 to 8.0 feet bgs at sample location SLD87286, located approximately 38 feet southwest of SLD70102.
- One potential preferential pathway associated with Area 11 was a former rail spur that was located in a historically low-lying area. The rail spur may have served to channel surface water east and west to or from the adjacent railroad tracks; surface water would then be anticipated to flow in a north-south direction along the Norfolk Southern and Burlington Northern Santa Fe railroad tracks.
- A water line exists along the southern property line of the South Tract, just south of the warehouse buildings located in the southwestern corner of the property, extending the distance of the South Tract southern border from Hall Street to Wharf Street. No specific test pits or sampling of the water line for migration assessment purposes were performed during the pre-design investigation; however, preferential pathway assessments are made during remedial construction activities. Other water

lines have been noted crossing the property (The Sanborn Map Company Inc., 1909). These lines do appear to cross the estimated radiological contamination area (if the lines still exist).

#### 4.4.2 Area 12

Area 12 (see Figure 4-C) is situated near the northeast corner of the large building complex situated in the southwest corner of the South Tract. The estimated radiologically contaminated area was defined based on gamma radiological walkover surveys and soil sample data that included three BNI samples (E2400N2000, E2362N1943, and E2394N1944) with  $SOR_{net}$  values equal to or greater than 1.0. Area 12 covers approximately 5,700 square feet (530 square meters). BNI surface sample location MC116 was located in the general area and had an  $SOR_{net}$  of 1.0. Samples were collected from sample location SLD06217 to verify the data from sample location MC116. Data from sample location SLD06217 resulted in an  $SOR_{net}$  of 0.3 and therefore failed to confirm the presence of radiological concentrations in excess of ROD RGs. Figure 4-C highlights the sample locations with  $SOR_{net}$  values equal to or greater than 1.0 and lists the  $SOR_{net}$  for each associated sample. The deepest contamination reported in Area 12 was noted at 2.0 feet bgs (E2394N1944). The sample from this location and depth was collected from a 1-foot interval instead of the typical 6-inch interval.

#### 4.4.3 Area 13

Area 13 (see Figure 4-C) is situated near the central portion of the South Tract. The estimated radiologically contaminated area was identified from results from the gamma radiological walkover survey and from three soil sample locations (HTZ00164, HTZ66299, and PSC00139). The area was bounded on the basis of other soil sample locations (SLD05727, MC117, HTZ66302, SLD70093, SLD06227, SLD05728, SLD06228, SLD06229, HTZ00165, SLD05733, and E2800N1945). The sample locations with  $SOR_{net}$  values equal to or greater than 1.0 and the  $SOR_{net}$  for each sample are provided on Figure 4-C. The deepest contamination reported in Area 13 was noted at 1.0 foot bgs (HTZ66299). Area 13 covers approximately 5,190 square feet (482 square meters). The primary COCs contributing to the radiological contamination in Area 13 were Ra-226 and Th-230. A potential preferential pathway was identified in the form of the rail spur crossing the area. Historical information has suggested that the rail spurs in the area may channel surface water runoff to surrounding areas. Radiological data for specific isotopes can be found in Table C-1.

#### 4.4.4 Area 14

Area 14 (see Figure 4-C) is situated along the northern rail spur within the South Tract. The area of estimated radiological contamination was identified from a potential Class 2 sample

App A.3.1 - PSC PDIR Rev1.doc

Small Area Remediation Work Area-Specific Description  
Appendix A.3.1 Pre-Design Investigation Data Summary Report  
PSC Metals Vicinity Property (DT-8)  
St. Louis Downtown Site

(SLD05720) collected in the area and was further delineated using historical and geological information, gamma radiological walkover survey data, and soil sample analytical results collected from sample locations in the area (SLD05723, SLD05717, and MC115). Area 14 covers approximately 900 square feet (84 square meters). Radiological contamination was estimated to extend to at least 0.5 feet bgs throughout Area 14. Historical information suggests that the contamination may extend farther to the east and west parallel to the rail spur feature. The primary COC contributing to the estimated radiological contamination noted at SLD05720 is Th-230. Contamination at sample location SLD05720 was reported from 0 to 0.5 feet bgs.

At sample location SLD69754, petroleum odors and staining were reported from approximately 2.0 to 6.0 feet bgs. This particular sample location did not contain radiological contamination and is located approximately 60 feet east of contaminated sample location SLD05720. Petroleum hydrocarbon-impacted soil might be expected if remedial excavation activities advanced toward the general area of SLD69754.

#### **4.5 Property Conditions – North Tract 4**

No areas of radiological contamination were identified within the top 6 feet bgs of the North Tract 4 at the DT-8 (see Figure 4-C). Several sample locations were found to exhibit elevated levels of radioactivity, but not at contaminant levels. Soil descriptions of the top 6 feet of material indicated that that material was fill of probable recent origin. Six sample locations (SLD72529, SLD72527, SLD72530, SLD72534, SLD72531, and SLD72532) situated within the North Tract 4 and 16 sample locations from surrounding properties were used to evaluate the tract.

#### **4.6 Property Conditions – East Tracts**

The East Tracts of the DT-8 consist of two small land tracts (designated as East Tracts 1 and 2 on Figure 4-D) located east of Wharf Street (Burlington Northern Santa Fe Railroad tracks) and south of the McKinley Bridge. Pre-design investigations conducted in and around the East Tracts were limited because previous remediations at several adjacent property tracts had extended into the DT-8 East Tracts properties, and contamination was removed (USACE, 1999). One area of radiological contamination (Area 15) was identified in the East Tract 2.

Data from samples surrounding and within the East Tract 1 indicate that elevated radioactivity existed in some areas but was not at sufficient concentration to be considered as radiological contamination. Field observation and analytical results indicate that the property and surrounding areas were likely excavated and filled recently. Analytical results from the upper

0.5 feet of soil throughout the property suggest that residual contamination is not present at that depth.

#### **4.6.1 Area 15**

Area 15 is located in East Tract 2 (Figure 4-D), which is situated east of the Burlington Northern Santa Fe Railroad, west of the Mississippi River, and north of Destrehan Street. The property covers approximately 13,800 square feet (1,282 square meters). Historical records indicated that previous remediation at adjacent properties extended into the East Tract 2 and shallow contamination was removed to a depth of approximately 6.0 feet bgs in the northern part of the land tract and to a depth of approximately 1.0 foot bgs in the southern part of the land tract (USACE, 1999). A sample collected from within the East Tract 2 during the pre-design investigation (post-remediation) from sample location SLD70486 indicated no contamination present at 0 to 0.5 feet bgs; however, contamination was noted from 0.5 to 1.0 foot bgs. Ra-226 was the primary contributor to the elevated  $SOR_{net}$ . Subsequent evaluation of this location via test pit methods indicated no contamination present at 1.2 to 1.5, 2.7 to 3.0, and 5.0 to 5.3 feet bgs. Note that 0.3-foot sample intervals were used here instead of the typical 0.5-foot interval. Contamination appears to be present from 0.5 to 1.2 feet bgs at SLD70486. Vertical delineation was achieved at sample location SLD70486. Sample location SLD76911 was a test pit sample location consisting of four samples (SLD76911, SLD76912, SLD76913, and SLD76914). Analytical results from this location indicated no contamination present from 0.2 to 0.5 feet bgs (clean fill from previous remediation), contamination present at 0.7 to 1.0 foot bgs (Ra-226 primary contributor to elevated  $SOR_{net}$ ), and no contamination present at 2.5 to 2.8 feet bgs and 5.2 to 5.5 feet bgs. Note that 0.3-foot sample intervals were used instead of the typical 0.5-foot interval. Contamination should be anticipated at 0.5 to 2.5 feet bgs throughout the estimated extent of contamination indicated in Area 15. Sample location SLD76918 was a test pit location at which four samples (SLD76918, SLD76919, SLD76920, and SLD76921) were collected. Analytical results from this location indicated no  $SOR_{net}$  values equal to or greater than 1.0.

The extent of contamination in Area 15 was vertically and horizontally estimated using the available soil sample results. Radiological contamination was estimated to extend to approximately 2.5 feet bgs throughout the designated contaminated area identified on the East Tract 2 (approximately 879 square feet [82 square meters]).

## **5.0 Summary and Conclusions**

---

The DT-8 consists of seven tracts of property owned by PSC Metals Company and situated in close proximity to the former MED/AEC operations conducted at the Mallinckrodt Chemical Corporation. One property tract, designated the South Tract (for the purposes of this report), was listed in the ROD as one of the original vicinity properties associated with the SLDS and cited by the ROD as requiring remediation from MED/AEC residual contamination. The USACE added the other PSC Metals property tracts to the SLDS project when it was determined that residual MED/AEC contamination may also have migrated to or been left on those properties. The USACE authorized a pre-design investigation be conducted at the DT-8 property tracts to determine the extent of radiological contamination identified during the remedial investigation, to identify and assess geological and historical deposits that may contain radiological contamination, and to more fully characterize the property tracts to allow remedial design to take place.

The pre-design investigation activities at the DT-8 were conducted between June 2000 and May 2001 (phase I), between May 2002 and January 2003 (phase II), and between September 2002 and June 2005 (phase III). As part of the 1999 Plant 6 East Half pre-design investigation, some samples were also collected on the DT-8 property. These sample locations have been included in this report. The pre-design activities included conducting background review and historical evaluations, conducting gamma radiological walkover surveys, soil sampling and analyses, waste characterization sampling and analyses, conducting site reconnaissance, and providing other ancillary support activities (e.g., surveying, mapping, site characterizations).

Based on the pre-design investigation activities authorized by the USACE, 15 areas of estimated radiological contamination were identified within the DT-8. North Tract 4 and East Tract 1 did not exhibit contamination, whereas the remaining five property tracts did. Contamination was estimated at depths ranging from the surface to 6 feet bgs on the eastern portion of Area 11. Additional sampling is required at seven of the 15 areas of radiological contamination to determine if residual radiological activity is less than ROD (USACE, 1998) RGs. These areas include Areas 4, 5, 8, 9, 12 (partial), 13, and 14. Sampling and analysis will be conducted in accordance with the FSSP (USACE, 2002). If RGs are exceeded, the area will be excavated as described in the Remediation Activity Work Description for this property.

<sup>1</sup> ft - feet

<sup>2</sup> bgs - below ground surface

<sup>3</sup> Analytical data includes background values (i.e., concentrations reflect gross radionuclide values)

<sup>4</sup> pCi/g - Picocuries per gram

<sup>5</sup> Prior to calculating the SOR, background values for each radionuclide were subtracted from their respective gross radionuclide values

Background Values:

|               |            |
|---------------|------------|
| Radium-226 -  | 2.78 pCi/g |
| Radium-228 =  | .95 pCi/g  |
| Thorium-230 = | 1.94 pCi/g |
| Thorium-232 = | 1.09 pCi/g |
| Uranium-238 = | 1.44 pCi/g |

If Detection Limit exceeds Result, ½ of Detection Limit was substituted for Result value in the SOR calculation.

*Samples in italics indicate MDA > Result*

Data presented in this Table were used solely for the purpose of delineating, vertically and horizontally, radiological COCs within the surface and subsurface soils.

<sup>E</sup> Estimated result. Result is less than the Detection Limit

<sup>I</sup> Matrix interference

ug/L- micrograms per liter

ug/kg- micrograms per kilogram

mg/kg - milligrams per kilogram

Deg. C - degrees celcius

TOX - total organic halogens

ND-Not detected above laboratory analytical detection limits

Analytical Methods:

TCLP Pesticides- EPA 8080

TCLP Volatiles- EPA 8260A

TCLP Herbicides- EPA 8150

TCLP Metals- EPA 7470/6010

PCB's- EPA 8082

Reactive Cyanide - EPA 7.3.3

Reactive Sulfide - EPA 7.3.4

Total Cyanide - EPA 9010A

TOX - 9020A

Note: A discrete soil sample was collected from sample location SLD06650<sub>4</sub> for the analysis of VOCs. Sample locations SLD06650<sub>1</sub> thru SLD06650<sub>5</sub> represent the five subsamples that make up the single composite sample.

KEY PLAN

LEGEND:

- SLDxxxxx = SAMPLE LOCATIONS WITH SOR VALUES  $\geq 1.0$
- HTZxxxxx = SAMPLE LOCATIONS WITH SOR VALUES  $< 1.0$
- SLDxxxxx = SAMPLE LOCATIONS (OUTSIDE OF SUBJECT PROPERTY)
- HTZxxxxx = SAMPLE LOCATIONS (OUTSIDE OF SUBJECT PROPERTY)
- HORIZONTAL LIMITS OF ESTIMATED DEPTH CONTOUR (FT BGS)
- 0.5— ESTIMATED MAXIMUM RADIOLOGICAL CONTAMINATION DEPTH CONTOUR (FT BGS)
- 1.0— ESTIMATED CONTOUR OUTSIDE PSC METALS BOUNDARY (FT BGS)
- AREA IDENTIFIED FOR ADDITIONAL SAMPLING IN ACCORDANCE WITH THE FSSP (TYPICAL)
- AREA OF HISTORICAL/GEOLOGICAL INTEREST (TYPICAL)
- AREA PREVIOUSLY REMEDIATED (TYPICAL)

KEYED NOTE:

1 PREVIOUS REMEDIATION OF THIS AREA RESULTED IN CLEAN BACKFILL BEING PLACED OVER AND AROUND THE NORTHERN PORTION OF THE AREA. CONTAMINATION IS ESTIMATED TO EXIST BELOW THE CLEAN BACKFILL. HISTORICAL SAMPLE LOCATIONS B16R140, B16W06 AND E3258N1500 HAD AN SOR NET VALUE  $\geq 1.0$ , BUT HAVE BEEN PREVIOUSLY REMEDIATED.

GENERAL NOTE:

SEE COVER SHEET (FIGURE 1) FOR GENERAL AND EXISTING UTILITY LEGEND AND ABBREVIATIONS (TYPICAL ALL FIGURES).
