ES.0 EXECUTIVE SUMMARY **1**

1.0 INTRODUCTION **7**

1.1 PURPOSE 7
1.1.1 Data Quality Objectives 8

1.2 SCOPE 10

1.3 REGULATORY FRAMEWORK 11

1.4 SITE BACKGROUND 12
1.4.1 Site Descriptions and Histories 12

1.5 PREVIOUS INVESTIGATIONS 17
1.5.1 AEC Investigations 17
1.5.2 USACE Investigations 19
1.5.3 Background Investigations 20

1.6 REPORT ORGANIZATION 22

2.0 SITE INVESTIGATION ACTIVITIES **36**

2.1 SURFACE FEATURES (NATURAL AND MANMADE, TOPOGRAPHIC MAPPING ETC.) 37

2.2 CONTAMINANT SOURCE INVESTIGATIONS 37

2.3 METEOROLOGICAL INVESTIGATIONS 38

2.4 SURFACE WATER AND SEDIMENT INVESTIGATION 38

2.5 GEOLOGICAL INVESTIGATIONS 38

2.6 SOIL INVESTIGATIONS 39

2.7 GROUNDWATER 41

2.8 RADIOLOGICAL INVESTIGATIONS OF BUILDINGS/STRUCTURES 41

3.0 PHYSICAL CHARACTERISTICS OF THE SITE **43**

3.1 GEOGRAPHY 43

3.2 DEMOGRAPHY 43

3.3 CLIMATE 43

3.4 TOPOGRAPHY, GEOLOGY AND SOILS 43
3.4.1 Topography 43
3.4.2 Geology 44

3.5 HYDROGEOLOGY 45
3.5.1 Regional Hydrogeology 45
3.5.2 Site Hydrogeology 45

ZnS	zinc sulfide

ES.0 EXECUTIVE SUMMARY

Remedial Investigation (RI) activities were conducted by the U.S. Army Corps of Engineers (USACE) Formerly Utilized Sites Remedial Action Program (FUSRAP) at eight areas of the Iowa Army Ammunition Plant (IAAAP). The eight areas within the scope of this RI report were at one time under the control of the former Atomic Energy Commission (AEC) and include:

- Firing Sites Area [(FS Area) consists of 5 subareas]
- Warehouse 3-01 (interior)
- Yard G
- Yard C
- Yard L (areas surrounding Warehouses L-37-1, L-37-2, and L-37-3)
- Yard E (portion)
- Yard F (portion)
- Area West of Line 5B (also referred to as "the former SECOM site")

The RI activities generated data, which when combined with applicable existing data, provided sufficient information in order to assess risks to various receptors within the eight areas. RI activities included a review of the available history and usage of the eight areas, development of Potential Constituents of Concern (PCOCs), soil sampling, gamma radiation walkover surveys, radiological structure surveys, contaminant risk evaluation, and development of this Remedial Investigation report.

ES.1 HISTORICAL REVIEW

Detailed reviews of historical usage of the eight areas within the scope of this RI were conducted in order to determine appropriate PCOCs. Results of these reviews are presented in the following work plan associated with this RI:

- *Remedial Investigation Work Plan for Line 1, Firing Sites, Yards C, G, and L, Warehouse 3-01 and the West Burn Pads Area South of the Road* (USACE, 2007).

Table ES-1 summarizes the historical review findings and subsequent PCOC determination originally presented in the above plan.

Table ES-1. Summary of Historical Review and PCOC Determination

RI Area	Historical Usage	Previous Investigations	PCOCs
Firing Sites			
FS-1 and FS-2	Administrative X-ray film processing.	Soils were sampled for metals during Supplemental RI (TN&A, 2002).	Metals
FS-3, FS-4, FS-5	Storage of munitions and DU components. Possible photographic development.	Soils were sampled for explosives during Supplemental RI (TN&A, 2002).	Metals Explosives Depleted Uranium (DU)
FS-6, FS-7, FS-8, and FS-15	Munitions and explosives testing.	Soils were sampled for metals and explosives during Supplemental RI (TN&A, 2002). Radiological surveys and sampling were conducted by USACE in 2001.	Metals Explosives DU

Table ES-1. Summary of Historical Review and PCOC Determination (Cont'd)

RI Area	Historical Usage	Previous Investigations	PCOCs
Firing Sites			
FS-12 Area (FS-9, FS-10, FS-11, FS-12)	Munitions and explosives testing.	DOE performed site visit in 2000 (ORNL, 2001). Radiological surveys and sampling were conducted by USACE in 2001. Soils were sampled for metals, explosives, and PCBs during Supplemental RI (TN&A, 2002).	Metals Explosives DU
FS-14	Munitions and explosives testing.	Soils were sampled for metals, explosives, and DU during Supplemental RI (TN&A, 2002).	Metals Explosives DU
Warehouse 3-01 (Interior)	Possible usage as overflow storage for items from Building 1-11 during AEC era.	None	DU
Yard G	Storage of raw and finished explosives products. Possible AEC-era storage of DU material.	USACE performed radiological surveys and soil sampling for DU in 2005 (USACE, 2007).	Metals Explosives DU
Yard C	Storage of raw and finished explosives products. Possible AEC-era storage of DU material.	DOE performed limited radiological surveys of selected Yard C buildings and storage igloos in 2000 (ORNL, 2001). USACE performed radiological surveys and soil sampling for DU in 2005 (USACE, 2007).	Metals Explosives PCBs DU
Yard L	Storage of raw and finished explosives products. Possible AEC-era storage of DU material.	USACE performed building surveys of Warehouses L-37-1, L-37-2, and L-37-3 in 2003 (USACE 2003). USACE performed radiological surveys and soil sampling for DU in 2005 (USACE, 2007).	DU
Yard E (portion)	Buildings E-13 and E-14 were at one time controlled by AEC. Possible storage of AEC-era DU.	None	DU
Yard F (portion)	Igloo F-9 was at one time controlled by AEC. Possible presence of DU.	None	DU
Area West of Line 5B (Former SECOM Site)	Area and building were at one time controlled by AEC. Possible presence of DU.	None	DU

Note: Line 1 and West Burn Pads Area (WBPA) South of the Road were originally included in RI work plan (USACE 2007a) but now are being addressed under existing IAAAP Record of Decision (RODs) and will not be evaluated in this RI Report. Data collected at Line 1 and WBPA South of Road were used to develop remedial designs consistent with ROD authority and are included in Appendix A Attachment 1 of this document and will be included in documents supporting remediation.

ES.2 FIELD ACTIVITIES AND FINDINGS OF THE REMEDIAL INVESTIGATION

As described in Section 2.0 of this report, a variety of field investigation methods were utilized to evaluate the presence of potential contaminants for areas within the scope of this RI. Primary investigation methods consisted of:

- *Gamma Radiation Walkover Surveys:* Gamma radiation walkover surveys (GWS) were conducted in outdoor portions of areas that had the potential to be impacted by DU. GWS were conducted using a sodium iodide gamma scintillation detector coupled with a Global Positioning System (GPS) unit in order to record both gamma radiation readings and geographic position data. Surveys were focused on areas most likely to have elevated levels of radioactivity such as areas adjacent to loading docks, along driveways, roadsides, and rail lines, as well as localized topographical low points such as ditches and depressions. In general, survey coverage was greater near expected sources of radiological contamination and decreased with distance from the expected source. This approach concentrated the greatest effort in the areas of highest risk and provided some coverage over other portions of the property.
- *Radiological Structure Surveys:* Structures with the potential to contain the presence of radiological (DU) contamination were surveyed. The structure surveys included scanning for total beta surface activity as well as taking fixed point measurements for total alpha and beta activity. In addition, collection of swipe samples for measurement of removable alpha and beta activity was conducted. Surveys were biased towards areas having the highest potential for radiological contamination such as entrances and exits, ventilation components, high traffic areas, cracks, floor drains, and loading/unloading areas.
- *Surface and Subsurface Soil Sampling:* Soil sampling was performed to assess both radiological and non-radiological constituents within the RI areas. Depending on the PCOCs for the area, samples were analyzed for explosives, metals, PCBs, SVOCs, and DU. In general, soil samples were biased toward areas judged to have higher potential for contamination than the surrounding area such as areas adjacent to loading docks, rail lines, driveways, roadsides, topographical low points, and areas where GWS has indicated elevated radioactivity.

Section 4.0 of this report presents the findings of the RI field activities. Data generated from the RI field activities were compared to appropriate screening values, e.g., U.S. Environmental Protection Agency (USEPA) Region 9 Industrial Preliminary Remediation Goal (PRGs), as presented in the corresponding work plan (*USACE, 2007*) in order to determine the need for additional evaluation or assessment of risk. Table ES-2 summarizes the RI field activities conducted in each RI area and presents constituents that exhibited at least one result above appropriate human health (i.e., PRG), ecological (i.e., critical concentration from the Baseline Ecological Risk Assessment (BERA), Iowa Army Ammunition Plant, Middletown, Iowa (*USACE, 2004a*)), or radiological screening values and have therefore been carried forward for further risk evaluation (as discussed in Section ES.3 as well as Section 6.0, *Baseline Human Health Risk Assessment*, Section 7.0, *Streamlined Ecological Risk Assessment*, and Section 8.0, *Baseline Radiological Risk and Dose Assessment*).

Table ES-2. Summary of Field Activities and Screening Value Exceedances

RI Area	Summary of Field Activities	Result
FS-1 and FS-2	GWS Soil sampling (metals) Soil sampling (DU) Building survey (radiological)	 No exceedance DU in soil (screening value exceedance) No exceedance
FS-3, FS-4, FS-5	GWS Soil sampling (metals and explosives) Soil sampling (DU) Building survey (radiological)	 No exceedance DU in soil (screening value exceedance) No exceedance

Table ES-2. Summary of Field Activities and Screening Value Exceedances (Cont'd)

RI Area	Summary of Field Activities	Result
FS-6, FS-7, FS-8, FS-15	GWS Soil sampling (metals and explosives) Soil sampling (DU)	 2,4,6 TNT in soil (PRG exceedances) RDX in soil (PRG exceedances) Chromium in soil (PRG exceedances) Aluminum in soil (PRG exceedance) DU in soil (screening value exceedances)
FS-12 Area (FS-9, FS-10, FS-11, FS-12)	GWS Soil sampling (metals and explosives) Soil sampling (DU) Building survey (radiological)	 No exceedance DU in soil (screening value exceedances) Exceedance of screening values for radiological survey of structure at FS-12.
FS-14	GWS Soil sampling (metals and explosives) Soil sampling (DU)	 No exceedance No exceedance
Firing Sites (whole)[1]	GWS Soil sampling (metals and explosives) Soil sampling (DU) Building survey (radiological)	 HMX (ecological CC exceedance) Antimony (ecological CC exceedance) Arsenic (ecological CC exceedance) Barium (ecological CC exceedance) Cobalt (ecological CC exceedance) Copper (ecological CC exceedance) Manganese (ecological CC exceedance) Thallium (ecological CC exceedance) No exceedance No exceedance
Warehouse 3-01 (Interior)	Building interior survey (radiological)	No exceedance
Yard G	GWS Soil sampling (metals, explosives) Soil sampling (DU) Building survey (radiological)	 HMX and mercury in soil (ecological CC exceedance) No exceedance No exceedance
Yard C	GWS Soil sampling (metals, explosives, PCBs) Soil sampling (DU) Building survey (radiological)	 HMX in soil (ecological CC exceedance) No exceedance No exceedance
Yard L	GWS Soil sampling (DU) Building survey (radiological)	 No exceedance No exceedance
Yard E (Portion)	GWS Soil sampling (DU) Building survey (radiological)	 No exceedance No exceedance
Yard F (Portion)	GWS Soil sampling (DU) Building survey (radiological)	 No exceedance No exceedance
Area West of Line 5B (Former SECOM Site)	GWS Soil sampling (DU) Building survey (radiological)	 No exceedance No exceedance

[1] Evaluation of ecological data was performed using data from the Firing Sites area as a whole.

ES.3 Baseline Risk Assessment

A Baseline Risk Assessment (BRA) was performed to determine current and potential future risks to human and ecological receptors that could result from soil exposures to site contaminants at IAAAP FUSRAP sites. The BRA evaluates current and future receptor exposures to soils

under existing baseline conditions by assuming no remedial actions, institutional controls, or engineering controls. Evaluations of groundwater or surface water exposures were not performed under the current scope of work. The BRA is presented as three separate components: Human Health Risk Assessment (HHRA) (Section 6.0), Streamlined Ecological Risk Assessment (ERA) (Section 7.0), and Radiological Risk and Dose Assessment (Section 8.0).

Human health dose and/or risks were calculated and evaluated in the HHRA and the Radiological Risk and Dose Assessment. During the HHRA and Radiological Risk and Dose Assessment, chemical and radiological constituents of potential concern (COPCs) in soil were identified. Generally, a COPC is a chemical or radionuclide retained for quantitative human health dose and/or risk evaluations. Constituents eliminated as COPCs were not quantitatively evaluated for dose and/or risk. The methods and criteria used for identifying COPCs in the HHRA and Radiological Risk and Dose Assessment are discussed in Sections 6.4 and 8.4, respectively. For the HHRA, soil COPCs were determined for each investigative area from a list of chemicals identified as having been detected in at least one sample at a concentration exceeding the corresponding USEPA Region 9 Industrial PRGs. Data comparisons with the Region 9 Industrial PRGs were discussed in Section 4. Data for those chemicals were then further evaluated in order to determine if those chemicals should be retained in the HHRA as COPCs by application of the following procedure: 1) an exposure point concentration (EPC) was derived for each chemical using the methodology described in Section 6.3.4; and 2) the resulting EPC for each chemical was compared to the corresponding Region 9 Industrial PRG. A chemical was retained as a COPC for quantitative risk evaluation if the EPC exceeded the Region 9 Industrial PRG. Based on the results of the COPC evaluation in the HHRA, Firing Site 6 was the only investigative area associated with COPCs that required further quantitative evaluation. The following chemicals were identified as COPCs in the HHRA at Firing Site 6: RDX, 2,4,6-trinitrotoluene, aluminum, and chromium.

In the Radiological Risk and Dose Assessment, the only COPC was depleted uranium (DU), which is composed of uranium-234 (U-234), U-235, and U-238. In Section 4 of this RI Report, U-234, U-235, and U-238 soil concentrations were evaluated against the radiological screening level to determine if an investigative area was radiologically impacted, if there was an environmental hazard associated with the DU, and if further investigation was needed. The firing sites (evaluated as one area in the Radiological Risk and Dose Assessment) was the only investigative area where DU contamination was located.

During the HHRA and Radiological Risk and Dose Assessment, chemical and radiological COPCs in soil associated with human health risk values exceeding USEPA's risk benchmark criteria were identified as constituents of concern (COCs) for further evaluation. Of the eight FUSRAP areas evaluated during this RI, human health risks exceeded USEPA's target risk criteria and COCs were determined for only the Firing Sites. Carcinogenic and noncarcinogenic risks exceeding USEPA's risk criteria for chemical exposures were limited to the Firing Site 6 (FS-6) area. Carcinogenic risks calculated for radiological exposures were determined for all of the Firing Sites combined (FS). Chemical and radiological COCs identified for the Firing Sites are summarized below:

- Current and Future Site Workers (Surface Soil, 0 to 1 ft bgs)
  - RDX (FS-6, 7, 8, and 15 Area)
  - 2,4,6-Trinitrotoluene (FS-6, 7, 8, and 15 Area)
  - Chromium (FS-6, 7, 8, and 15 Area)
  - DU (U-234, U-235, and U-238) (FS Area collectively)

- Future Construction Workers (Soil, 0 to 10 ft bgs)
  - 2,4,6-Trinitrotoluene (FS-6, 7, 8, and 15 Area)
  - Chromium (FS-6, 7, 8, and 15 Area)
  - DU (U-234, U-235, and U-238) (FS Area collectively)

In order to determine if chromium concentrations are comparable to background, EPCs were calculated for chromium in background soils (surface and 0 to 10 ft bgs). By comparing site chromium EPCs with background chromium EPCs, it was determined that the EPCs used to calculate risks for site worker and construction worker exposures to chromium in FS-6 soils exceed the corresponding background EPCs. Therefore, as indicated above, chromium was retained as a COC for both receptors.

Aside from human health, a Streamlined ERA was performed to evaluate soil chemical exposures to the Indiana bat *(Myotis sodalis),* a federally listed endangered species. Area EPCs were compared to critical concentrations (CCs) derived in the BERA (USACE, 2004a) for this receptor but recalculated in this Streamlined ERA. The comparisons were only performed for detected chemicals for which CCs had been derived in the BERA (USACE, 2004a). However, due to the prevalence of chromium detected at the Firing Sites, Eco CCs were derived for chromium in this Streamlined ERA.

EPC exceedances of CCs were determined for 2,4,6-trinitrotoluene and selenium at the Firing Sites, and HMX in Yards C and G. In both Yards C and G, CC exceedances occurred at single locations. The locations exhibiting Eco CC exceedances will be further evaluated for potential remediation in the FS.

The individual samples exhibiting exceedances of 2,4,6-trinitrotoluene or selenium Eco CCs are either within areas of active munitions testing (e.g., FS-6, 7, 8, and 15 Area) or immediately adjacent to actively used buildings (e.g., FS-1/FS-2, FS-14). The locations of the single exceedances in Yards C and G are immediately adjacent to storage igloos. Given the availability of better habitat at IAAAP, consideration must be given in the FS as to whether or not remediation of the fairly localized Eco CC exceedances at Yard C, Yard G, and the Firing Sites will positively affect the Indiana bat at the level of the individual receptor. Furthermore, continued industrial use can be an important consideration in the event that future operations in an area could continue to release contaminants into the environment, even if remediation has occurred in that area.

An uncertainty analysis was performed for chemicals without Eco CCs (some metals and explosives) that were detected in the evaluated areas. The analysis was based on prevalence (frequency of detection) and comparisons to background (metals). The results of this analysis suggest that there are no ecological concerns from chemicals without Eco CCs.

In summary, based on the results of the BRA, sites determined or associated with potential human health and/or ecological risk (the Firing Sites, Yard C, and Yard G) will be further evaluated in the Feasibility Study in a manner consistent with the CERCLA process.

1.0 INTRODUCTION

This Remedial Investigation (RI) Report was developed by the U.S. Army Corps of Engineers (USACE) Formerly Utilized Sites Remedial Action Program (FUSRAP) to address Atomic Energy Commission (AEC) related "releases or threats of releases of hazardous substances, pollutants or contaminants except for groundwater contamination" at the Iowa Army Ammunition Plant (IAAAP), near Middletown, Iowa (United States Environmental Protection Agency (USEPA), et al 2006). This report was prepared for USACE specific to Contract No. W912P9-06-D-0534 Task Order 0002.

Prior to conducting RI field activities the *Remedial Investigation Work Plan for Line 1, Firing Sites Area, Yards C, G, and L, Warehouse 3-01 and the West Burn Pads Area South of the Road* (USACE, 2007) consisting of Human Health Risk Assessment (HHRA) Work Plan, Quality Assurance Project Plan (QAPP), Data Management Program Plan (DMPP), and Health and Safety Plan (HSP) were submitted to the USACE on October 21, 2005. The Work Plan (WP) was approved by USACE and USEPA Region 7 and went final June 19, 2007. During implementation of the FUSRAP RI fieldwork, information regarding the use of Yards E and F, as well as the Area West of Line 5B (also referred to as "the former SECOM site") by AEC ("Report No.127" (January 1980)) was provided to USACE. These three areas are not included as "FUSRAP sites" in the FFA or other previous scoping documents; however, the Project Team decided that the appropriate action was to perform radiological surveys and sampling consistent with the approach used at the "blue sites." This methodology was described in the approach and has been added as Appendix G to the RI Work Plan (USACE, 2007).

RI field activities associated with the Remedial Investigation Work Plan (USACE, 2007) were conducted between October 23, 2006 and October 18, 2007. Results of these RI field activities, as well as results from previous investigations are summarized in this document. This RI report has been prepared in accordance with the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) of 1980 and the Superfund Amendments and Reauthorization Act (SARA) of 1986.

1.1 PURPOSE

This RI Report augments chemical (radiological and non-radiological) and explosives data obtained prior to designation of those portions of the IAAAP into FUSRAP. It defines the nature and extent of existing soil and sediment contamination as well as contamination of associated structures for areas within the scope of this document.

A Baseline Risk Assessment (BRA), including a HHRA and Streamlined Ecological Risk Assessment (ERA), as well as a Radiological Risk Assessment were performed to determine current and potential future risks to human and ecological receptors from exposure to site contaminants under baseline conditions (i.e., assuming no remediation has occurred, no institutional or engineering controls in place). Analytical results were validated to ensure that the data quality was adequate for use in the risk assessments. Conceptual site models were developed for the HHRA and the Streamlined ERA to aid in the selection and evaluation of receptors and routes of exposure. Constituents of Potential Concern (COPCs) were selected by screening the site analytical results against pertinent, published screening criteria. An exposure assessment was performed to quantify COPC intake for the receptors and pathways evaluated. A toxicity assessment was performed to obtain pertinent carcinogenic and non-carcinogenic toxicity factors to be used in the risk characterization, which is the final step of the risk assessment. The results from the HHRA, Streamlined ERA, and the Radiological Risk Assessment are presented in Sections 6, 7, and 8, respectively of this RI report.

1.1.1 Data Quality Objectives

The DQO process was developed by USEPA to facilitate collection of data that are important to decision making during environmental investigations. The work plan (USACE, 2007) follows the DQO process specified by USEPA in the "Guidance for the Data Quality Objective Process" (USEPA, 2000a). It can be defined as a series of planning steps designed to ensure that the type, quantity, and quality of data collected are appropriate for the intended purpose.

The DQO process was incorporated into the development and implementation of the field sampling plans detailed in this document. The following seven steps introduce the DQO process and discuss how it was used in this RI.

1) State the problem – The following concisely describes the problem studied:

   Historical data indicate the potential for radiological and chemical contamination in soil, sediment, and structures at seven investigative units at the IAAAP. These units were formerly used by Atomic Energy Commission.

2) Identify the decision – The following identifies the questions the study has attempted to resolve:

   - What are the potential contaminants of concern (PCOCs) based on the operational history of each site?
   - Which PCOCs were detected during previous investigations?
   - Which previously detected PCOCs should be retained because their detected concentrations exceed published, risk-based screening levels?
   - What is the nature and extent of the potential contaminants of concern (PCOCs)?
   - Are the existing data of sufficient quantity and quality to support risk assessment requirements?
   - Does the EPC for the area exceed published risk-based screening values?
   - Are there areas of an exposure unit that may need remediation?
   - What is the extent of the contamination that may need remediation?

3) Identify inputs to the decision – The following identifies information and measurements that were used to answer the study questions:

   - Historical operations at each site were reviewed to determine the PCOCs for each specific area based on the chemicals likely to have been used. Where appropriate, areas with multiple distinct operations and variable PCOCs (as in the Firing Sites) were subdivided into individual areas. Based on the operational history and PCOCs for each area, the locations for biased samples were chosen.
   - Existing data from all previous investigations were evaluated for usability.
   - Usable data from previous investigations were compared to published risk-based screening concentrations (e.g., 1.3 ppm for RDX in soil, 47.6 ppm for TNT in soil, and 30 ppm for arsenic in soil).
   - The screening level for DU has been established at 56 pCi/g. In accordance with NUREG 1507, this concentration represents the DU minimum detectable concentration (MDC) that will be detected by the average survey technician using a 2" x 2" sodium iodide (NaI) detector walking at a rate of 0.5 meters per second. In addition, conservative risk and dose assessment calculations for DU using RESRAD 6.0 under the residential scenario yield dose and risk to the maximum exposed individual of 5×10^{-5} and 8 millirem per year, respectively. Appendix A of the *Iowa Army Ammunition Plant Scoping Survey Plan for Firing Sites 6 and 12* (USACE, 2001) was consulted for more

information regarding soil concentration determination as well as other screening level risk/dose assessment information.

- PCOCs analyzed for but not detected were eliminated from further evaluation if it was determined that the samples had been collected at biased locations and the detection limits were at least as low as the screening value.
- New environmental samples were obtained during the FUSRAP RI from locations based on the operational history, the PCOCs to be analyzed, and the most likely locations at the site for detecting the PCOCs (biased sample locations), for example: operational points, building entrances, and drainage ways. Additional sample locations were selected, as necessary, to adequately provide for an evaluation of nature and extent of contamination and to fulfill data requirements.
- Additional environmental samples were collected to further delineate the nature and extent of contamination.

4) Define the study boundaries – Determines when and where the data should be collected:

- The horizontal study boundaries for the FUSRAP areas are identified on Figure 1-3).
- The vertical study boundaries were initially established based on the historical information for each site.
- The sampling interval was established based on data needs of the probable end user.
- The boundary area for delineation was determined after the collection of additional data and calculation of risk.

5) Develop a decision rule – Statistical parameters and decision criteria were defined.

- If an individual sample location exceeds the screening value for a contaminant, then further assessment was required to determine extent of contaminant; otherwise, no further evaluation is necessary.
    - Published risk-based screening concentrations have been established as conservative screening values for chemicals.
    - U-238 screening value has been established at 56 picocuries per gram (pCi/g).
- Laboratory Analysis –
    - Was used in conjunction with field screening parameters to verify the presence or absence of a contaminant.
    - Was used to provide information necessary for the evaluation of the nature and extent of a contaminant.
    - Specific parameters, analytical methods, and method detection limits were listed in Appendix D – Table 3.1 of the RI Work Plan (USACE, 2007).

6) Specify tolerable limits on decision errors – Tolerable error rates are defined.

Evaluation criteria for data quality were presented in Appendix D of the RI Work Plan (USACE, 2007), Quality Assurance Project Plan (QAPP).

7) Optimize the design – Generate alternative data collection designs.

Each round of sampling of the RI has been designed to lead to one of two decisions:

a) Additional actions are required to either determine nature and extent or to design a remedial action, or
b) No further evaluation is necessary.

Various methods of sampling were employed at the sites to fully optimize data collection.

Biased source point sampling was utilized in the base round of the RI to establish a location as requiring additional investigation or no further action. Biased source point sampling was

conducted in areas which have a high probability of environmental release of contaminants such as drainage pipes from buildings, areas of obvious staining, etc.

Composite biased source point sampling was utilized in the base round of the RI to establish if a large area source point requires additional investigation or no further action. Composite sampling was conducted in areas that did not have a single point of potential environmental release such as loading docks.

Biased accumulation point sampling was utilized in the base round of the RI to establish if an area upstream of the accumulation point had an environmental release and required further investigation or if no further action is necessary. Accumulation point sampling was conducted in areas of multiple source points with low probability of environmental release such as the ditches or sediment areas in Yard C or large areas with multiple potential sources.

Biased delineation sampling was utilized to determine vertical and horizontal extent of a contaminant that exceeds the screening value. Field screening was utilized to determine, in the field, the horizontal or vertical extent of the contaminant. Samples were obtained at the edge of the determined extent for laboratory analysis.

Trenching was utilized at FS-12 to determine soil horizons and the depth of soil disturbance to aid in determining the vertical study boundary for the base round or subsequent delineation sampling.

1.2 SCOPE

In September 1990, the US Army and USEPA Region VII entered into a Federal Facility Agreement (FFA) to define the roles and responsibilities for the Army's cleanup work at IAAAP and the process for inter-agency coordination. A second FFA was finalized on August 16, 2006, between USACE, USEPA Region VII, the Department of Energy (DOE) and the State of Iowa to address FUSRAP investigatory and cleanup work at IAAAP. The scope as defined in the FFA *"covers response actions at 7 areas associated with AEC activity."* The 7 areas that are defined in the FFA are shown on Figure 1-1 and include:

1. Line 1
2. Firing Sites Area (consists of 5 subareas)
3. West Burn Pads Area (South of the Road)
4. Warehouse 3-01 (Interior)
5. Yard G
6. Yard C
7. Yard L, areas surrounding Warehouses L-37-1, L-37-2 and L-37-3

According to the FFA for these 7 areas the USACE

> *"shall respond to all releases and threats of releases of hazardous substances, pollutants or contaminants, except for groundwater contamination.*
>
> *Other areas beyond those identified in this Section may be added to the list of areas subject to this Agreement if it is determined that they contain contamination resulting from AEC activities.*
>
> *Groundwater and surface water contamination on or from the Iowa Army Ammunition Plant, including such contamination associated with the 7 areas identified herein as FUSRAP area, is considered outside the scope, and shall be addressed pursuant to the IAAAP/Army FFA (Administrative Docket Number VII-F-90-0020)." (USEPA et al, 2006)*

The IAAAP sites investigated by FUSRAP include these 7 areas referenced in the FFA as well as three additional areas that were discovered during the course of the investigation. The three additional areas were found on a map depicting "Facilities That Were Used by the Former Burlington A.E.C. Energy Research and Development Administration (ERDA) Plant" (USATHAMA, 1980). The three additional areas that were identified for investigation are shown on Figure 1-2 and consist of portions of Yard E, Yard F, and the Area West of Line 5B. The RI Work Plan was supplemented by addition of an appendix that includes the three additional areas. This RI report addresses the investigative activities associated with all of these areas except the West Burn Pads Area (WBPA) (South of the Road) and Line 1, which were originally included in the RI work plan but are now being addressed under the existing IAAAP ROD and will not be discussed in the RI report. Data collected at Line 1 and WBPA South of the Road were used to develop remedial designs consistent with ROD authority and will be included in documentation supporting remediation. These data are included in Appendix A, Attachment 1 of this document to be consistent with requirements in the RI Work Plan (USACE, 2007). Figure 1-3 reflects all areas addressed by this RI report to include:

1. Firing Sites Area (consists of 5 subareas)
2. Warehouse 3-01 (interior)
3. Yard G
4. Yard C
5. Yard L, areas surrounding Warehouses L-37-1, L-37-2 and L-37-3
6. Yard E
7. Yard F
8. Area West of Line 5B (also referred to as "the former SECOM site")

The FFA (Section VI, "Findings of Fact", Paragraph B9) notes that "*In 2004, FUSRAP conducted a radiological screening survey of the Explosive Disposal Area, Inert Disposal Area, Demolition Area/Deactivation Furnace, and the Line 1 Former Waste Water Impoundment Area. The site screening survey of the 4 identified areas, completed in the fall of 2005 reported that these areas are free from radiological contamination and recommended elimination of these sites from further FUSRAP action. The FFA parties approved the "Final Summary of the Radiological Survey Findings for the Iowa Army Ammunition Plant Explosive Disposal Area, Inert Disposal Area, Demolition Area/Deactivation Furnace, and Line 1 Former Waste Water Impoundment Area," completed in the fall of 2005. These areas will continue under the control of the IRP remediation program and will not be part of this FFA.*" (USEPA et al, 2006) As such, the above four (4) areas are excluded from the scope of this RI Report.

1.3 REGULATORY FRAMEWORK

FUSRAP was created in 1974 to address sites used during the United States' early atomic energy program. Congress transferred the responsibility for administration and execution of cleanup at eligible FUSRAP sites to USACE in 1997. The IAAAP was proposed for inclusion on the National Priority List (NPL) pursuant to Section 105 of CERCLA on July 14, 1989, and was added to the NPL in August 1990. In March 2000, after performing historical research regarding AEC activities at the IAAAP, the U.S. Department of Energy (DOE) provided USACE with a determination that portions of the IAAAP may contain contamination resulting from activities that supported the nation's early atomic energy program. (The AEC including predecessor and successor agencies, conducted operations at the IAAAP from 1947 to 1975.) In July 2002, portions of IAAAP used by the AEC were designated by Congress as being eligible to be addressed by the FUSRAP. Upon designation into FUSRAP, the areas involved were removed

from the installation restoration program (IRP). FUSRAP work at IAAAP is being conducted by the USACE, St. Louis District under CERCLA.

1.4 SITE BACKGROUND

Detailed descriptions of the Firing Sites, Warehouse 3-01, Yard G, Yard C, Yard L, Yard E, Yard F, and the Area West of Line 5B, as well as the operational histories these sites are presented in Appendix C of the RI Work Plan (USACE, 2007), which is the companion document to this RI Report. The discussions provided in this section are intended to summarize the information previously documented by USACE (USACE, 2007).

1.4.1 Site Descriptions and Histories

The IAAAP is a government-owned contractor-operated facility that occupies approximately 19,000 acres in Des Moines County near Middletown, IA, approximately 10 miles west of Burlington, IA, and the Mississippi River (Figure 1-4). The IAAAP is one mile northeast of Augusta, Iowa and the Skunk River. IAAAP is under the command of the U.S. Army Joint Munitions Command, Rock Island, IL. The current operating contractor is American Ordnance, LLC.

The installation's mission is to load, assemble, and pack (LAP) ammunition items, including projectiles, mortar rounds, warheads, demotion charges, and munitions components such as fuses, primers, and boosters. Other activities performed at the installation include forestry, grazing, agriculture, and outdoor recreation, including hunting and fishing.

All of the IAAAP land is currently owned and under the control of the Army. Portions of the facility were previously under control of other tenant organizations including the Atomic Energy Commission. Approximately one-third of the IAAAP property is occupied by active or formerly active munitions production or storage facilities. The remaining property is generally either forested (7,500 acres) or leased for agricultural (7,700 acres) use.

Prior to the construction of IAAAP, the area was farmland. In November, 1940, the area was acquired by the Office of the Quartermaster General as the site for the Iowa Ordnance Plant (USATHAMA, 1980).

Since operations began in 1941, IAAAP has used explosives and lead-based initiating compounds to produce a wide variety of ordnance items. The Line 1 area, portions of the Firing Site (FS) area, the West Burn Pads (including West Burn Pads, West Burn Pads Landfill, Burn Cages, and the Burn Cage Disposal Area), the East Burn Pads, the North Burn Pad and Landfill, and Yards C, G, and L came under the jurisdiction of the Atomic Energy Commission [AEC; now the U.S. Department of Energy (DOE)] in 1947. In addition, the Security Command Center, the Emergency Response Command Post, the Deactivation furnace, Line 3 Warehouse 3-01, West Burn Pads South and the North Burn Pads Landfill might have been utilized. These areas were operated by the Burlington Atomic Energy Commission Plant (BAECP). The BAECP area as well as the rest of the site, was officially renamed the Iowa Army Ammunition Plant in 1963.

During the summer of 1947, Mason & Hanger - Silas Mason Company, Inc. entered into a contract with the Ordnance Department to assist in the design and engineering, to perform the construction, and to operate a facility for the purpose of supplying the Atomic Energy Commission (AEC) with explosive components for nuclear weapons. By the spring of 1949, IAAAP was at full production for high explosives fabrication (Mitchell, 2003). In March 1949, it was decided that certain weapon assembly operations (non-nuclear components) would also be

conducted at IAAAP (Poole and Harrison, 1954, Mitchell, 2003). Based on IAAAP Project History reports it is concluded that the first nuclear weapon assembly operations began in 1949. Throughout the remaining years the IAAAP tested, assembled, conducted surveillance and disassembled a wide variety of nuclear weapons. Entities that have operated the IAAAP include Day & Zimmerman Corporation (1941 to 1946), U.S. Army (1946 to 1951), Mason and Hanger Corporation (1951 to 1998), and since 1998, American Ordnance LLC.

1.4.1.1 Firing Sites Area Description and History

The Firing Sites Area (FS Area) is a fenced site that encompasses 450 acres (1,821,085 m^2) and is approximately one mile from the nearest installation boundary. The FS Area is located in the western portion of the IAAAP, and is bordered by Line 3A to the southwest and by the Inert Disposal Area (IDA) to the northeast. Several of the firing sites are currently in use by the Army. FS-6 is still being used for ordnance testing by the Army. FS-12 is not under current use and the remaining firing sites are being used for storage and operational activities.

The layout and topography of the FS Area are depicted on Figure 1-5. The surface elevations of the test firing pads in the FS Area range from 650 to 675 ft above mean sea level (U.S. Army Environmental Center 1996). The west and north branches of Long Creek converge within the FS Area prior to flowing into Mathes Lake. In general, surface water runoff from the FS Area flows east towards Long Creek or its two branches. Long Creek discharges to Mathes Lake approximately 1,000 ft from the southeast perimeter of the FS Area.

The FS Area was established as part of the Burlington Atomic Energy Commission Plant (BAECP) and was used for AEC activities between 1948 and 1974.

FS-1 and FS-2

FS-1 and FS-2 are located at the access point to the FS Area. FS-1 was used as an administrative facility and contained an x-ray film-processing machine to develop film of test shots. FS-2 was used as an inert storage facility (TN & Associates, Inc. 2002).

FS-3, FS-4, and FS-5

FS-3 and FS-4 were used for storage of munitions and radiological materials. FS-5 was a general-purpose storage magazine. No actual ordnance testing was done at any of these facilities. Components for hydro-shots were assembled at FS-5 during Atomic Energy Commission operations between 1965 and 1973. Hydro-shots consisted of conventional munitions surrounded by a large ring of depleted uranium (DU) that was broken, partially dissipated and scattered upon detonation. FS-3, FS-4 and FS-5 are currently used as storage magazines (USACE, 2001; TN & Associates, Inc., 2002).

FS-6, FS-7, FS-8, and FS-15

FS-6 is believed to have been the primary testing area until FS-14 was built in 1972. FS-7 and FS-8 are assumed to be observation bunkers based on engineering drawings. Historic drawings indicate the presence of an observation bunker and test fire pad at FS-6. Prior to the construction of FS-14, plane wave shots used to research explosive detonation waves were tested at FS-6. These shots did not contain any radioactive elements. The explosives used in these shots were Composition B and barium nitrate. Some tests at FS-6 involved explosive components, which contained a thin sheet of DU. The DU was expected to be pulverized and dispersed by the wind during these tests. The quantity of these tests conducted at FS-6 is unknown. Presently, FS-6 is used for the testing of ordnance.

FS-15 has little known information available due to operational security during Atomic Energy Commission operations (USACE, 2001). However, FS-15 was built to support copperhead testing (TN & Associates, Inc., 2002).

FS-9, FS-10, and FS-11

Little is known about these three sites. Historic drawings indicate that FS-9 was an underground observation bunker used in support of testing at the FS-10 test fire pad. FS-11 was an underground high explosive supply magazine. Remnants of an underground bunker were found at FS-11 during a site walkover conducted by TN & Associates, Inc. in November 2000.

FS-12

FS-12 was constructed by the Atomic Energy Commission to test hydroshots. A hydroshot was *a diagnostic operation that used DU as a surrogate for weapons-grade material, and was a quality control technique for measuring the performance for plastic bonded explosives (PBX) produced at IAAAP.* Records indicate 701 hydroshots occurred between 1965 and 1973 at FS-12, reportedly involving approximately 4,000 kg of DU (ATSDR 2003) with 530 hydroshots occurring between December 2, 1965, and March 3, 1969, 3 hydroshots under a different program presumably between March 4 and July 14, 1969, and 168 hydroshots between July 15, 1969, and December 31, 1973. Historical records indicate that at the conclusion of AEC activities at FS-12, residual DU soil contamination as high as 1746 picocuries per gram (pCi/g) existed at the site. Decontamination activities were subsequently conducted by the Mason & Hanger - Silas Mason Company, Inc.. This effort consisted of removal of soil at ground zero to a depth of 15 feet (ft); the removal of the top 1-2 inches of soil at an approximate radius of 30 to 50 ft around ground zero; and the plowing of the remaining FS-12 area. A letter from the Mason & Hanger - Silas Mason Company, Inc. dated September 20, 1974 shows the results of 12 post-remedial action samples taken from FS-12. This data set ranged from 2.4 to 335 pCi/g with a mean of 79 pCi/g and a standard deviation of 107 pCi/g and indicated that the 12 samples are "additional" post-remedial action samples.

From 1975 to November 2000, the Army used FS-12 for testing conventional weapons that did not contain DU (i.e., artillery shells, mines, and missiles). The Army halted all testing at FS-12 upon the discovery of DU in November 2000. Subsequent investigations identified numerous DU chunks on or near the surface at FS-12. The DU contamination appears to be the result of the hydro-shots because DU metal pieces found at FS-12 resemble portions of the DU ring used in the hydro-shots. In addition to DU, unexploded ordnance may exist at FS-12.

FS-14

FS-14 was used as a test firing range. Little information is available as to what was tested at FS-14 or when testing occurred. Information obtained indicates that tile shots and other testing were performed. Tile shots conducted during Atomic Energy Commission operations (no dates available) consisted of a relatively small amount of conventional explosives and boosters. FS-14 has little known information available due to operational security during Atomic Energy Commission operations (USACE, 2001).

1.4.1.2 Warehouse 3-01 Description and History

Warehouse 3-01 is located in the central portion of the IAAAP in the north-central area of Line 3. Warehouse 3-01 consists of a large brick building. The area of Warehouse 3-01 is approximately 0.64 acres (2608 m^2). The layout and topography of the area surrounding Warehouse 3-01 is depicted on Figure 1-6.

There is little written historical documentation concerning the operational history of Warehouse 3-01. Information obtained from the Project History of Line 1 indicates that the warehouse was

used as part of AEC operations (Ahlstrand, 1956). Site documentation indicated that Warehouse 3-01 was reactivated for temporary warehousing of overflow items from Building 1-11 (Mason and Hanger – Silas Mason Co. Inc., 1959). Warehouse 3-01 is currently in use by the Army.

1.4.1.3 Yard G Description and History

Yard G is located in the southern portion of the IAAAP and is bordered by Lake Mathis to the northwest, Yard K to the west and Yard E to the east. The area of Yard G is approximately 259 acres (1,048,103 m^2). The layout and topography of Yard G is depicted on Figure 1-7. Yard G is located in a heavily forested valley and contains storage igloos along the main access road. The access road runs in a horseshoe-like shape along the valley wall. In general, the land rises rapidly behind the igloos. Yard G consists of a small, relatively flat area around the igloo loading docks and associated driveways, and then drops steeply from the edge of the access road towards Long Creek at the bottom of the valley.

Yard G was constructed in 1942. AEC used the secured, fenced facility from 1948 until 1954 as a storage area for the finished castings of classified shapes with seven igloos having been used for this purpose (Mason & Hanger – Silas Mason Co., Inc., 1959). Yard G returned to Army control in 1975. No radioactive components were reportedly stored at Yard G. Yard G is currently in use by the Army.

1.4.1.4 Yard C Description and History

Yard C is located in the eastern portion of the IAAAP. It is bordered by the Boxcar Unloading Area and the Explosive Waste Incinerator to the north, Line 2 to the west and Yard D to the south. The area of Yard C is approximately 301 acres (1,218,291 m^2). The layout and topography of Yard C are depicted on Figure 1-8. Yard C consists primarily of 43 earthen igloos that are arranged in eight rows such that igloos are adjacent to rail lines and access roads. The igloos were built into the surrounding soil area making the low points of Yard C the adjacent rail lines (and associated drainage ditches) along each row of igloos.

Yard C was constructed in 1941-1942 to serve as a storage yard and consists primarily of an open field with 43 storage igloos. In 1947, Yard C came under the control of the AEC until 1975, which utilized the yard for storage of raw explosive materials and the sealed radiological components that were placed into the warheads. These raw materials were transported to Building 1-50 in Line 1. Building 1-50 served as a central transfer point prior to delivery to the Line 1 melt buildings. At an unknown date, probably prior to 1954, the necessary security was added to Yard C so that it became the only storage facility for both raw materials and finished products. No evidence was found to indicate that any releases of contaminants had occurred at Yard C. The Line 1 Project Histories (Mason and Hanger – Silas Mason Co. Inc., 1959) indicate that Yard C, was used for the storage of raw explosives material. These raw materials were transported to Yard C by rail in cardboard boxes with plastic liners. The rail lines are ditched for water drainage. The AEC performed a closeout survey of the 43 igloos in Yard C, finding no detectable contamination above background levels (USACE 2001). In 2000, DOE performed limited radiological surveys of Yard C Building 23-53, and Igloos 23-1, 23-2 and 23-3. No radioactive contamination was found during this survey (Oak Ridge National Laboratory (ORNL), 2001). Based on these results, DOE recommended that appropriate activities be conducted to complete a Multi-Agency Radiation Survey and Site Investigation Manual (MARSSIM) Class 3 building survey at Yard C (USACE, 2001). The aerial radiological survey conducted at IAAAP during October 2002 did not detect any anomalies at Yard C (U.S. Army Joint Munitions Command, 2003). Yard C is currently in use by the Army.

1.4.1.5 Yard L Description and History

Yard L is located about 1000 feet south of the northern boundary of the IAAAP. It is east of the "Administration Area", about 500 feet to the north of Lines 5A and 5B, and northwest of Line 1. The southeastern portion of Yard L was identified in the Technical Project Planning (TPP) Meeting for investigation by FUSRAP. The area of Yard L that is identified in this report is approximately 12 acres (48,268 m^2). The layout and topography of Yard L are depicted on Figure 1-9. Yard L consists of long buildings that run in an east-west orientation with railroad tracks that also run along the buildings for access. In general Yard L is flat with little changes in topography. Yard L is currently in use by the Army.

Portions of Yard L was used by the AEC to provide storage space for classified component parts starting in 1960 and Warehouse 21 was reportedly used for inert storage. A survey utilizing surface scans was conducted at Yard L on the AEC used warehouses in 2003 by USACE (USACE, 2003).

1.4.1.6 Yard E Description and History

Yard E is located in the south-central portion of the IAAAP. It is southeast of Line 800, about 1600 feet west of Yard D, about 2500 feet south of Line 2, and approximately 4300 feet north of the southern boundary of the IAAAP. Two buildings (Building E-13 and E-14) in the west-central portion of Yard E and the area between them were controlled by the Atomic Energy Commission / Energy Research and Development Administration (AEC/ERDA). These buildings are 2 of 34 buildings in Yard E that were constructed between 1937 and 1941. They are the fourth and fifth buildings from the north within the yard and are located immediately to the west of the second rail spur from the west boundary of yard as shown on Figure 1-10. This area of investigation is approximately 2.7 acres (11,108 m^2). AEC activities were not conducted in the other 32 buildings, but rather they were controlled by the Army contractor who at the time would have been Mason and Hanger-Silas Mason Co.

Although the nature of the operations performed at Yard E are not known, USATHAMA, 1980 indicates that "All buildings involved in the radioactive operations were surveyed prior to ERDA's departure (1 July 1975) and were found to be clean by contractor." It also notes that "The only real property identified as having been contaminated with radioactive material was FS-12 located in the north end of the FS Area." Nonetheless, no radioanalytical data records have been located for the Yard E area used by AEC/ERDA.

An aerial radiological survey of the IAAAP was performed in October, 2002 by the Department of Energy's Remote Sensing Laboratory with support from the personnel from Argonne National Laboratory. This survey used an aerial measurement system installed on a helicopter to assess the existence of radiological constituents on the facility. Yard E was one of three regions "with anomalously high results" with buildings in Yard E often coinciding with the highest detected gross counts. The report notes that "Inspections of gamma-ray spectra over Yard E sites show that depleted uranium is the major anthropogenic radioisotope present (U.S. Army Joint Munitions Command, 2003)." Further investigation into the results of the survey indicated that the elevated radioactivity measurements were the result of the on-going storage of DU kinetic energy penetrators in buildings within Yard E and were unrelated to AEC/ERDA activities.

1.4.1.7 Yard F Description and History

Yard F is located in the northwestern corner of the Iowa Army Ammunition Plant about 3000 feet and 4300 feet from the northern and western installation boundaries, respectively. It is about 2600 feet west of Yard H lies and to the northwest of the FS Area. The area of Yard F that was concentrated on for this report is approximately one acre (4,007 m^2). The portion of Yard F

utilized by the AEC/ERDA consists of the northernmost igloo in the westernmost north-south row of igloos. This igloo is designated as Igloo F-9 as shown on Figure 1-11.

No records were found by USACE regarding the Atomic Energy Commission operations at Yard F. USATHAMA, 1980 indicates that "All buildings involved in the radioactive operations were surveyed prior to ERDA's departure (1 July 1975) and were found to be clean by contractor." Review of historical photos of the Yard F area indicates that igloos were constructed between 1937 and 1941 with minimal visible change in the area used by AEC from the time of bunker construction until 1998, the date of the most recent aerial photograph. Road access is by means of roads which enter the yard area from the east in the central portion of the yard area. Access roads include a road around the perimeter of the Yard F site.

1.4.1.8 Area West of Line 5B Description and History

The Area West of Line 5B (also referred to as "the former SECOM site") is described by USATHAMA, 1980 as being among "Facilities that were used by the Former Burlington A.E.C. (ERDA) Plant." The Area West of Line 5B is between Yard J on the south and the "Administration Area" on the north and is located about 1000 feet west of the Line 5B boundary. The area is approximately 39 acres (157,061 m^2). This area includes one building, Building 600-86, which has been removed by the Army as part of the Facility Reduction Program in 2007(after FUSRAP remedial investigation activities). This building was located near the northeast corner of the area as indicated on Figure 1-12. This structure is clearly present on a 1969 aerial photograph but is not apparent on a 1963 aerial photograph thus it appears as if the building was erected during this six year period and was likely erected by the AEC. Review of aerial photographs from 1937, 1950s, 1963, 1969, and 1978 fail to provide evidence of operational facilities within this area other than those associated with the aforementioned building. As with other areas incorporated into this RI effort, the nature of the operations performed within this area was not found in the historical documents available. However, USATHAMA, 1980 indicates that "All buildings involved in the radioactive material operation were surveyed prior to ERDA's departure (1 July 1975) and were found to be clean by contractor."

1.5 PREVIOUS INVESTIGATIONS

1.5.1 AEC Investigations

Various environmental investigations have been conducted at IAAAP since the 1970s. An investigation to document the presence of beryllium was conducted by AEC from 1970 to 1973. Beryllium was thought to have originated as dust on incoming component parts that had not been adequately cleaned prior to shipment to the facility (TN & Associates, Inc. (TN&A), 2002).

In 1975, the AEC surveyed the buildings before releasing them back to the IAAAP. According to the June, 2000 report to the congressional defense committee, the AEC surveyed the 43 igloos in Yard C before the facilities were returned to the army in 1975.

Site Investigation (SI), RI and feasibility study (FS) activities were conducted at the IAAAP, by Jaycor under contract to the United States Army. In August 1991, an IRP SI was conducted for each of 43 areas having known or suspected contamination based on previous investigations and knowledge of operational and waste handling practices. In 1992 and 1993, a Remedial Investigation/Feasibility Study (RI/FS) was conducted for IRP under the management of the United States Army Environmental Center, with results presented in the *Revised Draft Final Remedial Investigation/Risk Assessment, Iowa Army Ammunition Plant, Middletown, Iowa* (U. S. Army Environmental Center, 1996).

The results of the Phase I RI conducted from July through November 1992 were used to refine the soil and groundwater investigation in the Phase II RI, which commenced in April 1993. Phase I and II RI results indicated that collection of additional data was necessary to further characterize the nature and extent of on-site contamination. The supplemental field effort was conducted in April through August 1995 and consisted of the placement of additional soil borings and groundwater monitoring wells, soil sample collection adjacent to previously unsampled explosives wastewater sumps, shallow soil sampling to verify positive results from the soil gas sampling during the Phase I RI, and collection of stream gauging data and shallow groundwater levels to characterize the hydraulic connection between surface water and shallow groundwater. The May 1996 Revised Draft-Final RI Report (U.S. Army Environmental Center, 1996) was accepted as final in accordance with the IRP FFA.

In October 1997, an Interim Record of Decision (ROD) that addresses IAAAP site soils as Operable Unit (OU) 1 was signed by the USEPA and the Army IRP (U.S. Army Environmental Center, 1997). The Interim ROD (U.S. Army Environmental Center 1997), utilized data collected by Jaycor. The Interim ROD is currently in effect and is the decision document under which current IRP remedial actions are being performed (IAAAP, 2005). The Interim ROD addresses one of the principal threats posed by the soil OU by temporarily placing for future treatment the most highly contaminated soils in the on-site Corrective Action Management Unit (CAMU). The CAMU is constructed to meet the specifications of the Resource Conservation and Recovery Act (RCRA) Subtitle C landfill requirements. The remaining contaminated soils will be permanently disposed of in either the on-site Soil Repository, which is also constructed to RCRA Subtitle C landfill specifications, or the on-site inert landfill (U.S. Army Environmental Center, 1997).

In 2000, ORNL performed indoor surveys of selected structures at Line 1 and Yard C on behalf of the DOE. The objective of the surveys were to determine if residual radioactivity from previous AEC activities was present and to conduct sampling in those areas of previous AEC operations that utilized radioactive components. The sampling data was used to evaluate any possible immediate health hazards as well as to collect sufficient information to determine the next type of survey required. In addition to gamma walkover surveys, soil samples were field screened for radioactivity and submitted for radionuclide analyses. Systematic air samples, in addition to biased debris and smear samples, were also collected from some buildings for radionuclide analysis. Systematic samples were collected without regard to radiation level; biased samples were collected at locations of elevated beta-gamma levels.

The building surveys included surface beta-gamma scans of accessible areas inside buildings, a scan of greater than 80% of floor surfaces with a floor monitor probe, a scan of less accessible areas with a beta/gamma pancake probe, and direct measurement of gamma, alpha, and beta-gamma radiation levels inside the buildings. About 1% of the wall surfaces in each room were scanned for both alpha and beta-gamma radiation using portable instrumentation where areas of floor contamination were found. Some overhead structures were also surveyed for both alpha and beta-gamma radiation with the extent of such surveys depending on the quantity of contamination detected on floor areas. Measurements were also made on miscellaneous structures such as air ventilation systems, floor drains, equipment, and window sills. Special attention was given to surveys of areas where contamination typically collects (e.g., cracks, joints, and corners) (ORNL, 2001).

Findings of these surveys were published in *Results of the Indoor Radiological Survey of the Iowa Army Ammunition Plant, Middletown, IA*, July 2001 (ORNL, 2001). The surveys concluded that there was no DU contamination present in Yard C (ORNL, 2001). Although this was to be only an indoor survey, the surveyors did visit FS-12 in preparation for a planned

outdoor survey and found obvious signs of DU contamination (two small fragments) on the ground surface. The report concluded that all other buildings surveyed at Yard C were recommended for a Final Status Survey per MARSSIM (ORNL, 2001). On March 30, 2000, the DOE provided USACE with a determination that portions of the IAAAP utilized by the BAECP potentially contained contamination resulting from activities that supported the Nation's early Atomic Energy Program.

1.5.2 USACE Investigations

The USACE St. Louis District completed a Preliminary Assessment (PA) (USACE, 2001) in 2001 to determine the need for further action by the USACE, under FUSRAP, to ensure protection of human health and the environment at the IAAAP. The PA focused on the review of Hazardous, Toxic, and Radiological Waste (HTRW) generated by AEC activities and included scoping radiological surveys of Firing Sites 6 and 12 to augment historical site assessments. Soil contamination was found to be non-uniform consisting primarily of chunks, subsequently confirmed to be depleted uranium, throughout FS-12 and in two locations at FS-6. The PA identified the need for additional investigation into potential radioactive, chemical, and explosives contamination at specific areas at the IAAAP. Preliminary Assessment data is included in the *Preliminary Assessment, Iowa Army Ammunition Plant, Middletown, Iowa* (USACE, 2001).

During 2002, a supplemental RI for Line 1 and the FS Area was completed by the IRP for chemical (non-radiological) constituents. The results of the TN & Associates RI are published in the *Draft Final Line 1 and Firing Site Supplemental Remedial Investigation Report* (TN&A, 2002). Their efforts included a five-month long search of the historical operation and production activities and chemicals used at Line 1. In addition to the historical research, the analytical results from the initial RI conducted previously by JAYCOR in 1996 were used in developing the rationale behind sample collection and chemicals to be measured. Areas of potential chemical releases were determined, soil samples were collected from these areas and chemically analyzed, and chemical results were evaluated and reported in the aforementioned report. This investigation was conducted to further delineate the extent of contamination in support of future IRP remedial designs/investigations for removal of contaminated material (TN&A, 2002). Much of the history presented herein has been taken from TN & Associates' *Supplemental RI Work Plan* (TN&A 2001) and *Supplemental RI Report* (TN&A, 2002).

TN&A collected surface and subsurface samples for analyses for explosives and metals from drainage ways that lead to Brush Creek in an effort to investigate explosives and metals concentrations associated with the possible movement of washout into Brush Creek. Although barium was detected above its preliminary remediation goal (PRG) at one location, metals were not detected above action levels at other locations. Samples from Brush Creek exhibited explosives above detection limits but no explosive samples exceeded remediation goals (RGs) at any of the 26 locations. (TN&A, 2002)

An aerial radiological survey of the entire IAAAP was conducted during October 2002 by the Army under the IRP to assess, within the limits of the detector system, the nature and extent of gamma emitting radioisotopes, both man-made and natural. The survey objective was to identify areas that had been affected by a release of anthropogenic radioactive sources and to assist in determining areas that not been impacted. (U.S. Army Joint Munitions Command, 2003). Results of the survey were used to confirm that there is no detectable contamination in areas that are thought to be free of contamination and to provide information for further site delineation between FUSRAP and IRP. Potential contaminants of concern (PCOCs) for this survey included DU (primarily uranium-238), radium-226, plutonium-239, and associated fission products.

Results of the aerial radiological survey indicated the presence of anthropogenic sources at Yard E, the Coal Pile at the heating plant, and at FS-12. DU was identified at Yard E, and is the probable radioisotope at FS-12. Low activity and the relatively small area of the FS-12 source resulted in poor statistics for the net spectrum; however, the spectrum was consistent with DU. The radioactivity observed at the Coal Pile is likely from naturally occurring radioactive materials that are present in the coal (USACE, 2005b). No additional areas that require inclusion under FUSRAP, rather than IRP, were identified during this survey (U.S. Army Joint Munitions Command, 2003). Generally, the GWS conducted during the RI reflects the results of the aerial survey by showing no radiological risks at any FUSRAP site except for FS-12.

In February 2003, USACE St. Louis District (FUSRAP) conducted a site reconnaissance survey to determine the radiological status of Yard L warehouse buildings L-37-1, L-37-2, and L-37-3 in support of site maintenance. The survey which applied only to actual building interior and exterior structures, confirmed the absence of detectable radiological contamination present in or on the warehouse surfaces (USACE, 2003).

Data collected to support an ecological baseline risk assessment in 2004 is published in the *Baseline Ecological Risk Assessment, Iowa Army Ammunition Plant, Middletown, Iowa* (USACE, 2004a).

In August 2004, USACE St. Louis District (FUSRAP) conducted a radiological survey to investigate selected areas at the IAAAP that were identified and defined within the PA (USACE, 2001) as being impacted and warranting further investigation for potential radioactive contamination. These areas were identified as the EDA [which includes the West Burn Pads Area (including West Burn Pads, West Burn Pads Landfill, Burn Cages, and Burn Cages Disposal Area), the East Burn Pads, and the north Burn Pad and Landfill], the IDA, the Demolition Area/Deactivation Furnace (DA/DF), and the Line 1 Former Waste Water Impoundment. It was confirmed that none of the four areas were impacted with radiological contaminants from AEC operations. These sites are commonly referred to as the "Blue Sites" and are discussed in the *Summary of the Radiological Survey Findings for the Iowa Army Ammunition Plant Explosive Disposal Area, Inert Disposal Area, Demolition Area/Deactivation Furnace, and Line 1 Former Waste Water Impoundment Area* dated June 6, 2006 (USACE, 2006).

1.5.3 Background Investigations

Generally, site remediation is not expected to be performed to levels below naturally occurring background levels. For the determination of background radionuclide concentrations, and as described in the *Iowa Army Ammunition Plant Scoping Survey Plan for FS Firing Sites 6 and 12*, a reference area was selected to determine background uranium levels at the site located northeast of IAAAP Gate 4 directly behind Casey's General Store. The reference area was selected upon agreement of the USACE, IDPH, and USEPA Region 7 representatives. Seven locations were sampled within the reference area (Figure 1-13). All soil samples were analyzed for gamma emitting isotopes and processed for alpha spectroscopy analysis to determine the isotopic concentrations of all three uranium isotopes present in DU (U-238, U-235, and U-234). The soil sample alpha spectroscopy analysis results for the uranium isotopes are shown in Table 1-1.

Table 1-1. Reference Area Soil Sample Results for Background Levels of Radionuclides

Reference Area Data Summary			
	U-234 pCi/g	**U-235 pCi/g**	**U-238 pCi/g**
Mean	1.19	0.04	1.36
Median	1.35	0.03	1.42

1) Field duplicate
2) Field split

Previous environmental investigations have included a sampling and analysis effort for the determination of naturally occurring background levels of inorganic elements (nonradionuclides) in soil. For this RI report, the background inorganics data for soil that were presented and applied in the BERA (USACE, 2004) are being used for comparison purposes. A statistical summary of these data are presented in Table 1-2, with a detailed presentation included as Appendix A, Attachment 3 for this RI Report.

Table 1-2. Statistical Summary of Inorganics Data for Background Soil

Inorganic	Number of Samples	Minimum (mg/kg)	Maximum (mg/kg)	Mean (mg/kg)	Standard Deviation (SD) (mg/kg)	Mean + 1SD (mg/kg)	Mean + 2SD (mg/kg)	Mean + 3SD (mg/kg)

1.6 REPORT ORGANIZATION

This RI report is prepared in accordance with USEPA guidance and their recommended format (USEPA, 1988). Further direction was provided in the Statement of Work provided by USACE. The report consists of an Executive Summary, Sections 1 through 9 and Appendices.

Section 1 describes the purpose and organization of this report, presents a site description and historical information, including previous investigations performed at the site. The objective is to provide a historical perspective to be used in evaluating human health and environmental impacts associated with the IAAAP areas.

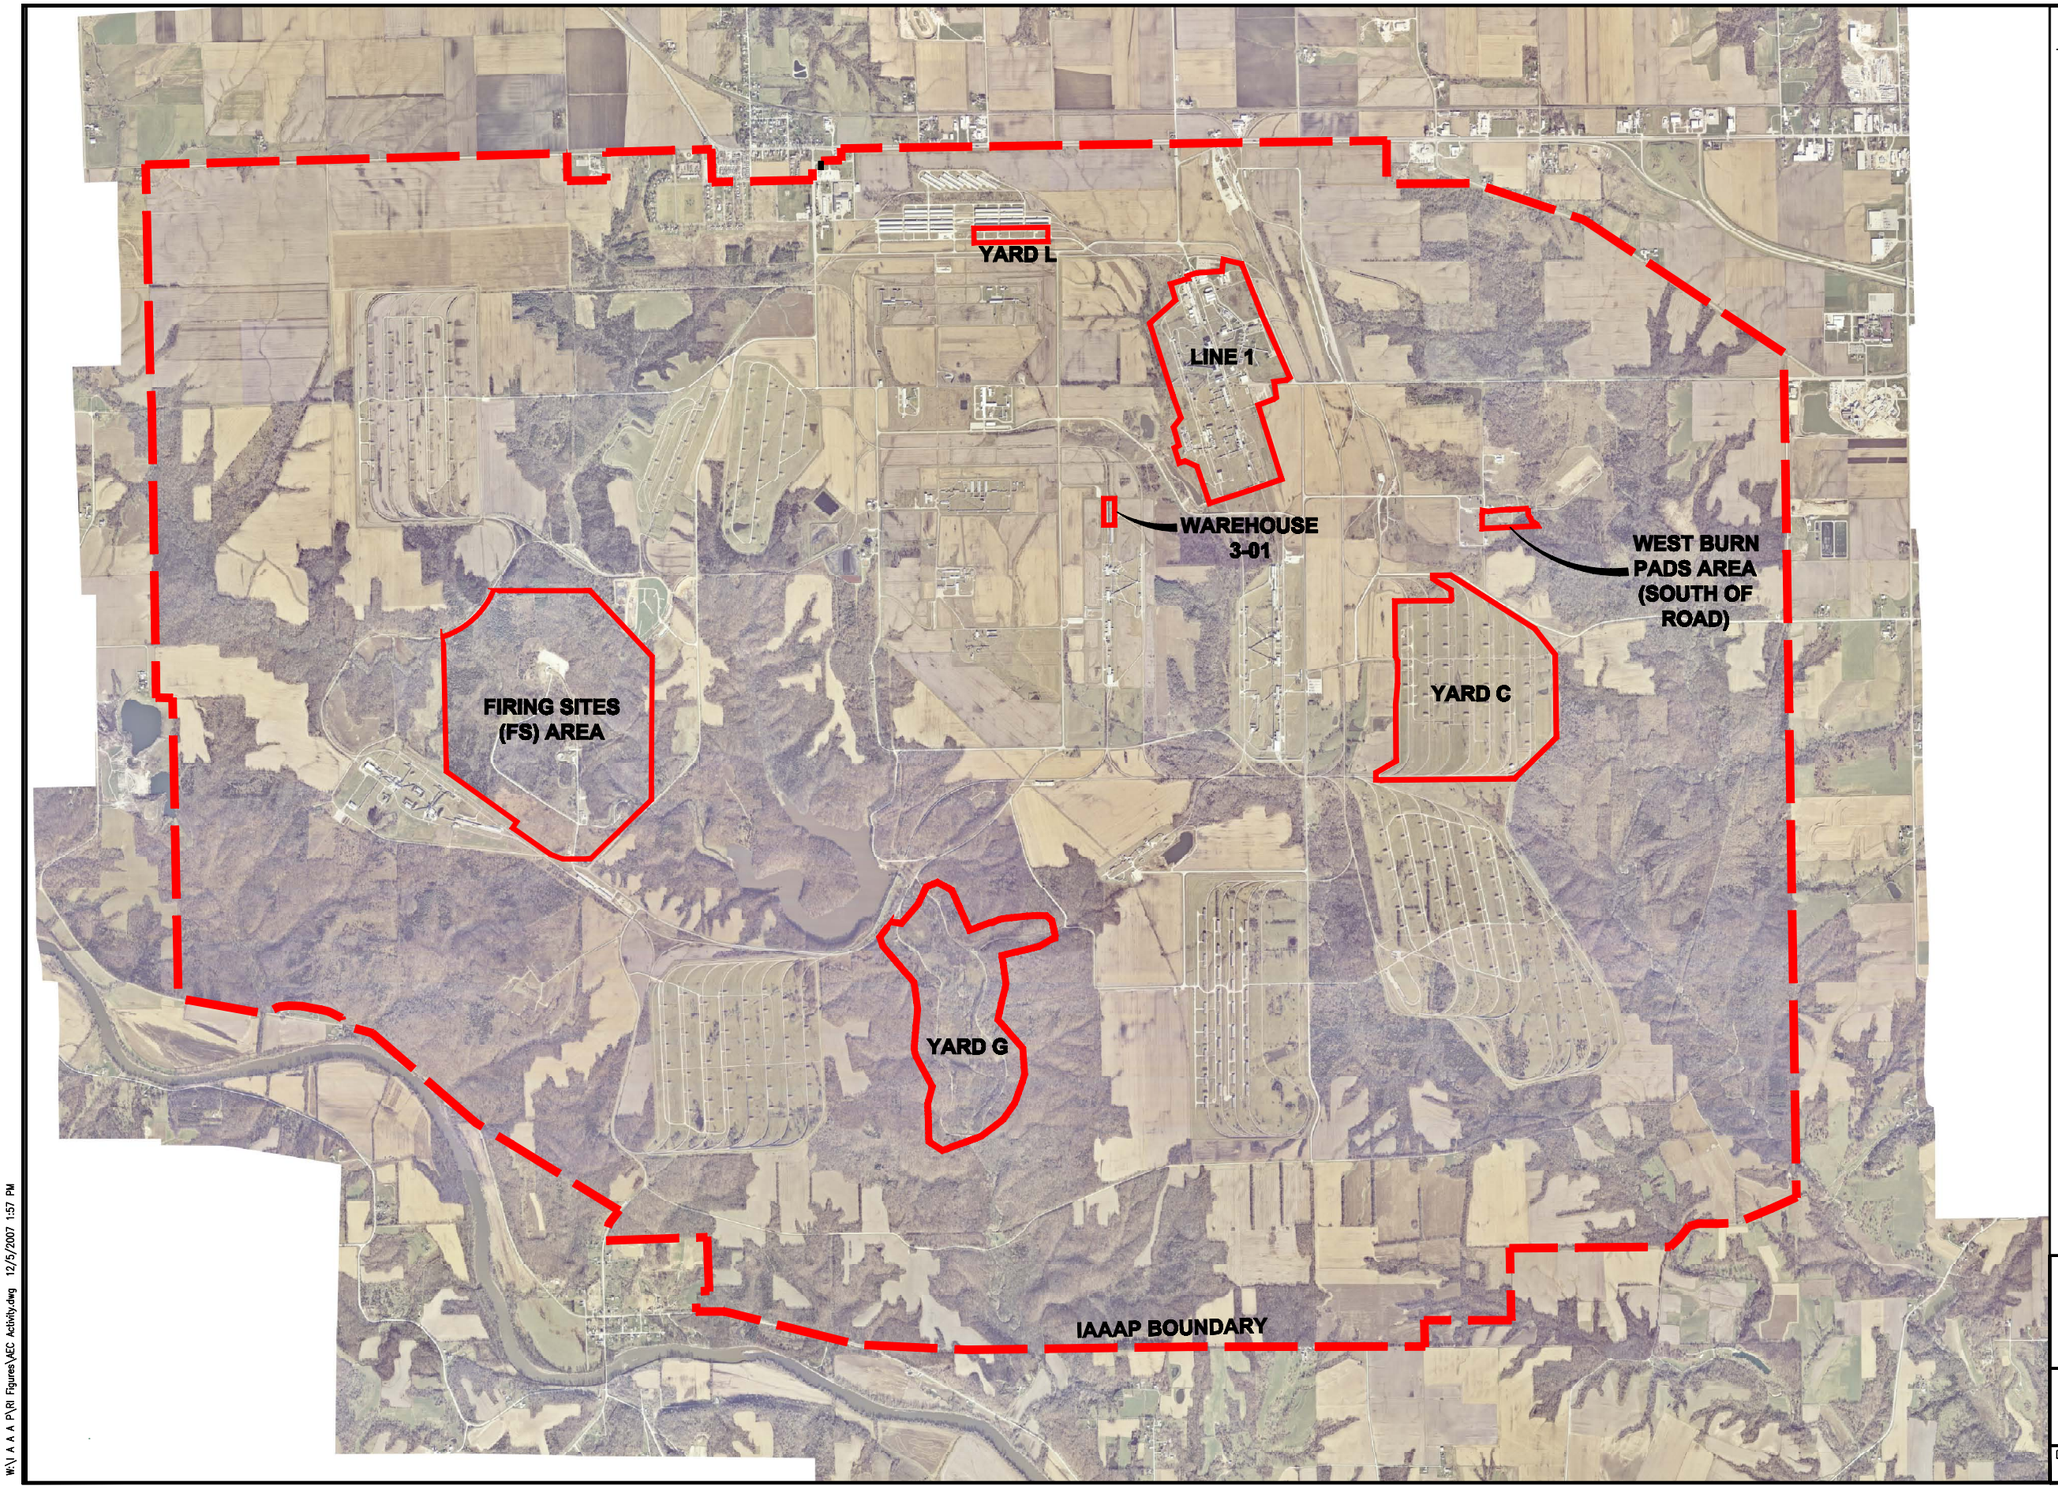
Section 2 describes physical characteristics of the IAAAP site, including geography, geology, hydrology, and ecology of the study area.

Section 3 describes the environmental investigations conducted to support the RI. The following field activities are summarized in this section: sampling and radiological measurements.

Section 4 presents a discussion of the nature and extent of contaminants detected at each of the FUSRAP investigated areas.

Section 5 presents an evaluation of the fate and transport of selected site constituents. The physical and chemical characteristics impacting fate and transport with respect to the various site media are summarized in this section.

Section 6 presents the HHRA for the BRA. Data evaluations supporting the risk assessment and the uncertainties associated with the HHRA are presented in Section 6.



Section 7 presents the Streamlined ERA for the BRA. Data evaluations supporting the risk assessment and the uncertainties associated with the Streamlined ERA are presented in Section 7.

Section 8 presents the Radiological Risk Assessment for IAAAP. Data evaluations supporting the Radiological Risk Assessment and the uncertainties associated with it are presented in Section 8.

Section 9 presents the summary and conclusions.

Section 10 lists the references used in the preparation of this document.

The appendices contain relevant IAAAP site specific data. Detailed analytical data for the FS Area, Yard G, Yard C, Yard E, Yard F, and a the Area West of Line 5B is presented in Appendix A. Appendix A, Attachment 1, presents the figures for Line 1 and West Burn Pads Area South of the Road. Detailed analytical data for Line 1 and WBPA South of the Road is presented in Appendix A, Attachment 2. The metals background data appears in Appendix A, Attachment 3. A quality control summary report (QCSR) is presented in Appendix B. Appendix C presents HHRA calculation tables. Appendix D presents copies of field sampling logbooks. Appendix E presents photographs taken during soil trenching activities at FS-12. Appendix F presents RESRAD input/output files.

2.0 SITE INVESTIGATION ACTIVITIES

As described in Section 1.5 several previous investigations have been conducted in the areas of concern covered by this RI Report. In order to eliminate redundancy, data from previous investigations were evaluated and used as appropriate to support the completion of this RI. An extensive historical document review was conducted to gather as much information as possible. In summary, this RI Report fully utilizes all data obtained by investigations performed under the authority of the Formerly Utilized Sites Remedial Action Program but also utilizes all other appropriate, available data, irrespective of source.

RI Field Activities Summary

The following RI activities were conducted at IAAAP:

- Conducted gamma walkover surveys at the FS Area covering approximately 24.5 acres (99,200 m^2) area.
- Obtained 13 fixed point radiological readings and swipes for buildings at the FS Area.
- Collected and analyzed 82 surface and subsurface soil samples for DU at the FS Area.
- Collected and analyzed 76 surface and subsurface soil samples for metals at the FS Area.
- Collected and analyzed 89 surface and subsurface soil samples for explosives at the FS Area.
- Collected and analyzed 4 surface soil samples for polychlorinated biphenyl (PCB) at the FS Area.
- Conducted gamma walkover surveys at Yard G covering approximately 16 acres (64,000 $m^{2)}$ area.
- Obtained 48 fixed point radiological readings in buildings at Yard G.
- Obtained 24 swipes from buildings at Yard G.
- Collected and analyzed 13 surface soil samples for DU at Yard G.
- Collected and analyzed 13 surface soil samples for metals at Yard G.
- Collected and analyzed 13 surface soil samples for explosives at Yard G.
- Conducted gamma walkover surveys at Yard C covering approximately 15 acres (60,000 m^2) area.
- Obtained 42 fixed point radiological readings and swipes at Yard C.
- Collected and analyzed 15 surface soil samples for DU at Yard C.
- Collected and analyzed 21 surface soil samples for metals at Yard C.
- Collected and analyzed 26 surface soil samples for explosives at Yard C.
- Collected and analyzed 1 surface soil sample for PCBs at Yard C.
- Conducted gamma walkover surveys at Yard L covering approximately 8 acres (33,200 m^2) area.
- Collected and analyzed 6 surface soil samples for DU at Yard L.
- Conducted gamma walkover surveys at Yard E covering approximately 2 acres (8,800 m^2) area.
- Obtained 20 fixed point radiological readings and swipes from buildings at Yard E.

- Collected and analyzed 12 surface soil samples for DU at Yard E.
- Conducted gamma walkover surveys at Yard F covering approximately one acre (4,000 m^2) area.
- Obtained 14 fixed point radiological readings and swipes from Igloo F-9 at Yard F.
- Collected and analyzed 12 surface soil samples for DU at Yard F.
- Conducted gamma walkover surveys at the Area West of Line 5B covering approximately 1.2 acres (5,100 m^2) area.
- Obtained 13 fixed point radiological readings and swipes at the Area West of Line 5B.
- Collected and analyzed 13 surface soil samples for DU at the Area West of Line 5B.

The totals for the areas covered by this report are as follows:

- Conducted gamma walkover surveys over approximately 68 acres (274,300 m^2) area at IAAAP.
- Obtained 150 fixed point radiological readings and swipes at IAAAP.
- Collected and analyzed 153 surface and subsurface soil samples for DU at IAAAP.
- Collected and analyzed 108 surface and subsurface soil samples for metals at IAAAP.
- Collected and analyzed 125 surface and subsurface soil samples for explosives at IAAAP.
- Collected and analyzed 5 surface soil samples for PCBs at IAAAP.

2.1 SURFACE FEATURES (NATURAL AND MANMADE, TOPOGRAPHIC MAPPING ETC.)

After review of the data presented in the *Iowa Army Ammunition Plant Revised Draft Final RI* (JAYCOR, 1996) and the *Line 1 and Firing Site Supplemental Remedial Investigation Report* (TN&A, 2002), it was determined that the available information on surface features of the targeted areas was adequate for the purposes of this investigation and no additional field investigation was necessary to gather additional information. It was determined that the existing base maps were sufficient for the purposes of the investigation.

2.2 CONTAMINANT SOURCE INVESTIGATIONS

In accordance with USEPA's *Guidance for Conducting Remedial Investigations and Feasibility Studies Under CERCLA* (Table 3-13 - Suggested RI Report Format). Section 3.2.3 of the USEPA Guidance states that source characterization involves the collection of data describing (1) facility characteristics that help to identify the source location, potential releases, and engineering characteristics that are important in the evaluation of remedial actions; (2) the waste characteristics, such as the type and quantity of contaminants that may be contained in or released to the environment; and (3) the physical or chemical characteristics of hazardous wastes present in the source. Contaminant source data and information presented in the *Iowa Army Ammunition Plant Revised Draft Final RI* (JAYCOR, 1996) the *Line 1 and Firing Site Supplemental Remedial Investigation Report* (TN&A, 2002), and the *Remedial Investigation Work Plan for Line 1, Firing Sites Area, Yards C, G, and L, Warehouse 3-01, and the West Burn Pads Area South of the Road* (USACE, 2007) were sufficient in quantity and quality that no additional field investigations were conducted to gather additional information on contaminant sources for the site. The available information was adequate for the purposes of this investigation.

2.3 METEOROLOGICAL INVESTIGATIONS

After review of the data presented in the *Iowa Army Ammunition Plant Revised Draft Final RI* (JAYCOR, 1996) and the *Line 1 and Firing Site Supplemental Remedial Investigation Report* (TN&A, 2002), it was determined that the available information was adequate for the purposes of this investigation and no additional effort was necessary to gather additional information on meteorological conditions at the site.

2.4 SURFACE WATER AND SEDIMENT INVESTIGATION

After review of the data presented in the *Iowa Army Ammunition Plant Revised Draft Final RI* (JAYCOR, 1996) and the *Line 1 and Firing Site Supplemental Remedial Investigation Report* (TN&A, 2002), it was determined that the available information was adequate for the purposes of this investigation and no additional effort was necessary to gather additional information on surface waters of the targeted areas. However, sediment samples were collected, in accordance with the RI Work Plan, in ditches and drainages containing water-transported sediment using the following steps:

- Don clean gloves and using a stainless steel spoon, or other approved utensil, remove surface vegetation and debris from the immediate area around the marked sampling point.
- Use plastic sheeting around work area, as necessary, to prevent equipment from contacting with potentially-contaminated surfaces.
- Record the appropriate information and observations about the sample location in the field logbook.
- Using a pre-cleaned or decontaminated stainless steel scoop or spoon to collect a grab sample and composite it in a stainless steel bowl.
- Depending on the analytes of interest, collect a sufficient volume of soil to satisfy the requirements of Table 4.1 of the QAPP as shown in Appendix D of the RI Work Plan (USACE, 2007).
- Label the sample using a unique identification number. A sequential Sample Number will follow the Site Designator code to identify the samples for collection and delivery to the laboratory.
- Complete all chain-of-custody documents and record the sampling event in the field logbook.
- Decontaminate sampling equipment after use and between sampling locations.

Groundwater and surface water contamination on or from the Iowa Army Ammunition Plant, including such contamination associated with the areas identified herein as FUSRAP area, is considered outside the scope, and shall be addressed pursuant to the IAAAP/Army FFA (Administrative Docket Number VII-F-90-0020) (USEPA et al, 2006).

Results of the sediment analyses are incorporated within Section 4, Nature and Extent of contamination.

2.5 GEOLOGICAL INVESTIGATIONS

After review of the data presented in the *Iowa Army Ammunition Plant Revised Draft Final RI* (JAYCOR, 1996) the *Line 1 and Firing Site Supplemental Remedial Investigation Report* (TN&A, 2002), no additional field investigations were conducted to gather additional information on geological conditions at the site. It was determined that no additional geological

investigations were necessary to determine the nature and extent of contamination in the target areas. Area specific geophysical data may be necessary for remedial design, but were not deemed necessary to determinate nature and extent of contaminants.

2.6 SOIL INVESTIGATIONS

Soil investigations consisted of surface and subsurface soil sampling for both radiological and non-radiological constituents as well as gamma radiation walkover surveys. Investigations to assess the presence of non-radiological potential constituents of concern (PCOCs) within areas of the IAAAP that are within the scope of FUSRAP investigations included the collection of surface and subsurface samples analyzed for explosives, metals, semivolatile organic compound (SVOCs), PCBs, and polycyclic aromatic hydrocarbon (PAHs). Results of the soil and vadose investigations are included in Section 4 (Nature and Extent of Contamination).

Soil investigation for radiological assessment was conducted by random and systematic soil sampling across the site to assess the presence of radiological constituents. Then gamma walkover radiation surveys were performed to assess the presence of radiological constituents in surface soils. Next, soil sampling for radiological assessment was conducted in areas that exhibited elevated gamma count rates (from the gamma walkover surveys).

Soil sampling was performed using a number of sampling techniques, including sampling by scoop and sampling with a hand auger. The general procedure for each of these soil sampling methods is addressed in this section of the report.

For the purposes of this RI, surface soil samples were collected and composited over a depth interval of 0 to 6 in. (15 cm) below ground surface (bgs). Subsurface soil samples were collected at discrete 6 in. intervals or composited over appropriate depth intervals.

Soil Coring Method or Scoop – This method was used to collect soil samples [to 6 in (15 cm) bgs]. The following steps were followed for this sampling methodology.

- Don clean gloves and using a stainless steel spoon, or other approved utensil, remove surface vegetation and debris from the immediate area around the marked sampling point.
- Use plastic sheeting around work area, as necessary, to prevent equipment from contacting potentially-contaminated surfaces.
- Record the appropriate information and observations about the sample location in the field logbook.
- Using a pre-cleaned or decontaminated stainless steel soil coring tool (or stainless steel scoop) collect a grab sample and composite it in a stainless steel bowl.
- Depending on the analytes of interest, collect a sufficient volume of soil to satisfy the requirements of the QAPP.
- Label the sample using a unique identification number. A sequential Sample Number will follow the Site Designator code to identify the samples for collection and delivery to the laboratory.
- Return any excess soil cuttings to the sampling location.
- Complete all chain-of-custody documents and record the sampling event in the field logbook.
- Decontaminate sampling equipment after use and between sampling locations.

Hand Auger/Tube Sampler – This method was used to collect soil samples [> 6 in (0.15cm) bgs, as appropriate]. The following steps were followed for this sampling methodology.

- Assemble a decontaminated auger and advance the auger bit into the soil to the depth desired.
- Withdraw auger.
- If a sample is not desired, remove soil from auger. If a sample is to be taken in the next interval, replace the auger bit with a pre-cleaned or decontaminated bit and repeat the above steps.
- Remove the auger and collect the soil sample.
- If the sampling device contains more than 1 sample volume (i.e., the amount of soil by volume that will completely fill one sample container for laboratory analysis), the soil should be homogenized before being transferred to the sample container. If less than 1 sample volume is collected, two or more samples of the interval should be composited.
- Depending on the analytes of interest, collect a sufficient volume of soil to satisfy the requirements of the QAPP.
- Label the sample using a unique identification number. A sequential Sample Number will follow the Site Designator code to identify the samples for collection and delivery to the laboratory.
- Return any excess soil cuttings to the sampling location.
- Complete all chain-of-custody documents and record the sampling event in the field logbook.
- Decontaminate sampling equipment after use and between sampling locations.

Decontamination procedures depended upon the type of sampling performed with the equipment. The first two steps listed below were used for all sampling equipment. The following steps depended on whether the equipment was used for radiological sampling or chemical sampling. If the equipment was used for chemical sampling, it was washed and dried as described. Radiological sampling equipment was surveyed such as to assure there was no residual removable radioactivity from previous sampling.

- Remove all visible dirt/debris or sample residue from sampling equipment.
- Wipe sampling equipment with dry towel or baby wipe.
- Decontaminate with water, acid, soap, alcohol, and air dry, as prescribed in EM 200-1-3.
- Perform a loose surface contamination measurement on sampling equipment.
- Ensure loose surface contamination levels are less than 20 dpm/swipe.
- Return sampling equipment for future use.

Gamma Walkover Survey - A Ludlum Model 44-10 2" sodium iodide (NaI) gamma scintillation detector coupled with a Global Positioning System (GPS) (or equivalent) was used for performance of the gamma walkover scans. Screening gamma walkover scans focused on areas most likely to have elevated levels of activity as determined by the survey supervisor. The surveyor advanced at a speed of approximately 2 feet (ft) (0.5 meters) per second while passing the detector 4-6 in above the ground surface. Scanning results were recorded in counts per minute (cpm). The survey coverage was greater near the expected radiological source point or areas having the highest potential to contain residual radiological contamination. If no elevated gamma radiation levels were encountered, the gamma scan coverage decreased with increased distance from the suspected

source. This approach concentrated the greatest effort in the areas of highest risk and still provided some coverage over other portions of the property.

Audible responses of the instrument were monitored, and locations of elevated audible response were investigated. The initial investigation level for the gamma scans was set at 3,000 cpm above the relative background for the given area. The investigation level was adjusted by the survey supervisor with USACE concurrence based on the deviation of count rates encountered as the survey progressed. This investigation level was entirely dependent upon the relevant background in each specific area. Locations exceeding the investigation level were investigated and, if appropriate, sampled. Gamma scan data was recorded in real time using position and data recording methods.

2.7 GROUNDWATER

As previously stated in Section 2.4, groundwater and surface water contamination on or from the Iowa Army Ammunition Plant, including such contamination associated with the FUSRAP areas addressed within the RI report, is considered outside the scope, and shall be addressed pursuant to the IAAAP/Army FFA (Administrative Docket Number VII-F-90-0020)." (USEPA et al, 2006). As such, investigation of groundwater was not included in the scope of this RI.

2.8 RADIOLOGICAL INVESTIGATIONS OF BUILDINGS/STRUCTURES

Radiological surveying of structures was conducted to determine the presence, if any, of radiological contamination. Radiological surveys included scanning for total beta surface activity and fixed point measurements for total alpha and beta surface activity using portable radiological survey equipment, and collection of swipe samples for measurement of removable alpha and beta activity. Results of the radiological investigation of buildings/structures are provided in Section 4.

Uranium has associated alpha, gamma, and beta radiations, which can be used to identify the presence of residual contamination and estimate the concentrations potentially present at the IAAAP. Beta scans were used because alpha radiation is a less reliable indicator of true surface activity levels due to greater attenuation. A Ludlum Model 2360 coupled with a Ludlum 43-89 (zinc sulfide (ZnS) plastic scintillator) (or equivalent) was used for performance of the beta scans. The scan speed with these detectors was approximately 1 to 2 inches per second. Distance from the detector probe to the surface being scanned was approximately 0.25 inch. Instrument response was continuously monitored during scanning through use of the audible instrument signal. Scanning results were recorded in cpm, which along with the appropriate instrument geometry and calibration information was used to convert the data to dpm/100cm^2 for comparison to criteria.

Screening beta scans were generally performed over accessible areas. For the purposes of this report, accessible is defined as areas where safety considerations or other restrictions do not prevent access for normal scanning activities. The beta scan surveys were biased to areas with the highest potential for contamination based on the professional judgment of the Survey Supervisor.

Total alpha-beta surface activity (fixed-point) measurements were conducted as necessary based on the results of the beta scans. Fixed-point gross beta activity measurements were made with 30 second static counts using a (43-89) ZnS plastic scintillator. The results of the survey for both alpha and beta were recorded in cpm and converted to dpm upon completion of the survey.

Removable alpha and beta activity was measured by smearing an area of approximately 100 cm^2 with a dry filter paper; alpha and beta activity on the smear sample was then measured. Removable alpha and beta surface activity samples (smears) were collected at each fixed-point measurement location. The smear was collected, counted for radioactivity, and documented prior to conclusion of the survey.

Survey locations were limited to only those areas that are reasonably accessible for personnel and instrument safety. Areas covered by this survey were:

- entrances and exits;
- ventilation;
- sumps and floor drains;
- high traffic areas; and
- shipping and receiving loading and offloading areas.

Beta scan surveys were conducted by moving the detector at 1 to 2 inches per second and with the active area of the detector approximately 0.25 inches from the surface being surveyed. If the investigation level (80% of the screening level) was reached during scanning, the surveyor paused to allow the instrument response to stabilize. A biased fixed-point measurement and smear was performed where elevated activity was noted (and confirmed) during the scan survey. Activity was calculated using the following equations:

$$\text{ncpm} = \text{gcpm} - \text{bcpm}$$

where:

ncpm = net counts per minute
gcpm = gross counts per minute
bcpm = instrument background counts per minute

$$\text{dpm}/100\ \text{cm}^2 = \frac{\text{ncpm}}{\varepsilon_i \times \varepsilon_s \times \text{DA}} \times \frac{100\ \text{cm}^2}{100\ \text{cm}^2}$$

where:

DA = detector area
ε_i = instrument efficiency (cd-1)
ε_s = surface efficiency (unitless)
Ludlum 43-89 detector area = 125 cm^2

The effects of self-absorption may produce considerable error in the reported surface activity levels. A surface efficiency (εs) of 0.5 (unitless) for beta and 0.25 for alpha was used based on recommendations found in NUREG-1507, Section 5.3.2.

For the purpose of the surveys conducted during this RI, any structure exhibiting fixed point measurement(s) that exceeded the screening values of 600 dpm/100cm^2 alpha or 6000 dpm/100cm^2 beta not due to radon and associated daughters were subjected to additional evaluation.

3.0 PHYSICAL CHARACTERISTICS OF THE SITE

3.1 GEOGRAPHY

IAAAP is located near Middletown, Iowa (see Figure 1-4), in Des Moines County. Middletown, Iowa is located at Latitude 40°49'41"N, and Longitude 91°15'37" W. According to the United States Census Bureau, the city has a total area of 0.6 square miles. IAAAP consists of approximately 19,000 acres and has security fencing around the entire facility.

3.2 DEMOGRAPHY

According to the U.S. Census of 2000, there were 535 people that reside in Middletown, Iowa. The population density was 130.7 people per square mile (338.6/km^2). The median age was 36 years. The median income for a household was $37,083. The per capita income for the city was $16,835. About 19.5% of the population was below the poverty line, including 28.8% of those under age 18 and 16.0% of those age 65 or over.

3.3 CLIMATE

The IAAAP experiences climate typical of the Midwest where winters are cold and wet followed by hot and humid summers. The mean annual temperature for this area is 51.8 degrees Fahrenheit (^{o}F) with a minimum recorded temperature of -27^{o}F and maximum recorded temperature of 111^{o}F. Annual average precipitation is 40.6 in. and is generally well-distributed throughout the year providing ample water for abundant vegetation growth and numerous ponds and lakes in the area. The facility has a historical high of 48.2 in. of annual precipitation recorded in 1947 and a historical low of 25.8 in. recorded in 1963 (TN&A, 2001). The month of March is typically the windiest month and May and June are typically the wettest. The prevailing wind across the IAAAP is from the south with an average speed of 12 miles per hour. The site is located in an area of moderate tornadic activity frequency, according to the United States Weather Service (TN&A, 2001).

3.4 TOPOGRAPHY, GEOLOGY AND SOILS

3.4.1 Topography

The IAAAP is located within the Southern Iowa Till Plains section of the Central Lowland Province Drift Plain Region. The general topography of the area is characterized by gently undulating terrain due to continental glaciation and is incised with dendritic drainage patterns. Site topography ranges from flat tier at the northern portion of the facility to steep-sloped drainage ways down to creek beds at the southern portion of the facility. The central area of the IAAAP consists of flat to rolling terrain dissected by shallow drainage ways (U.S. Army Environmental Center, 1996). There are three main creeks, Brush, Long, and Spring Creeks, that range in width from roughly 50 to 200 feet (ft). These streams, along with unnamed tributaries feeding these streams, sculpt the land surface in a dendritic drainage pattern.

According to the U.S. Geological Survey, the topographic elevation of the IAAAP ranges from a highpoint of 730 ft above mean sea level at the northern portion of the facility to a low of 530 ft above mean sea level at the creek beds to the south (U.S. Army Environmental Center, 1996). The site has an approximate topographic relief of 200 ft with a regional slope trending toward the south-southeast (U.S. Army Environmental Center, 1996).

3.4.2 Geology

3.4.2.1 Regional Geology

A description of the regional geology is derived from the boring log of Water Well 4 in the northern portion of the facility that was advanced to a depth of 1,932 ft (USACE, 2001). The overlying unconsolidated material consists of approximately 137 ft of clay (note: the percentage of sand, silt, or gravel was not reported during this analysis). Bedrock underlying the unconsolidated material is characterized as a sequence of limestones interbedded with varying thicknesses of shales and sandstones. The uppermost bedrock unit is the Keokuk Limestone of the Mississippian Osage Series and is characterized as gray to buff interbedded limestone and chert (TN&A, 2001).

Beneath the Keokuk Limestone lies the following sequence of formations with their respective thicknesses: Kinderhook (Maple Mill) Shale at approximately 168 ft thick; Cedar Valley Limestone at approximately 170 ft; Wapsipinican Shale at approximately 27 ft; Maquokota and Galena Limestone at approximately 214 ft; Glenwood Sandstone at approximately 9ft; unnamed shale at approximately 37 ft; St. Peter Sandstone at approximately 141 ft; unnamed zone of cherty, dolomitic limestone at approximately 538 ft which contains within it an approximately 3 ft thick shale seam, an approximately 3 ft thick sandstone seam, and an approximately 3 ft thick shale seam; Jordan Sandstone of the Cambrian System at approximately 149 ft; and an unnamed limestone at the bottom of Water Well 4 at an unknown thickness (TN&A, 2001).

3.4.2.2 Site Geology

The IAAAP is located within the Dissected Till Plain section of the Central Lowland Province of the Southern Iowa Drift Plain Region. The facility is underlain by a sequence of unconsolidated deposits of Pleistocene age overlaying sedimentary bedrock units. Glacial till in this area is comprised mostly of silty clay and clayey silt with thin sand seams and lenses. These tills are associated with the Illinoian age Kellerville Till Member of the Glasford Formation and extend to depths exceeding 100 ft in some areas of the northern portion of the facility. However, the tills thin considerably and are locally absent to the northeast and in deeper stream valleys to the south around Mathes Lake (USACE, 2001).

The depth of glacially derived windblown silt (loess material) across the IAAAP ranges from approximately 6 to 15 ft. The Kellerville Till has a minimum thickness of 35 ft. According to the Iowa Geologic Survey, the Kellerville Till is subdivided into a superglacial and subglacial (i.e., basal) till facies, based on stratigraphic relations, sedimentological properties, and the consistency-density-consolidation properties of deposits. The basal till unit is described as silty clay, gray to yellowish-brown in color, with a trace to little sand (USACE, 2001).

The underlying bedrock of the IAAAP ranges in age from Cambrian to Mississippian and is comprised of a sequence of limestones interbedded with varying thicknesses of shales and sandstones. The uppermost bedrock unit underlying the facility is associated with the Southern Iowa Mississippian Osage Series. This series is composed mostly of cherty limestones interstratified with small amounts of shale. The Osage Series is divided into the Warsaw Formation, Keokuk Limestone, and Burlington Limestone. The Warsaw Formation consists primarily of blue-gray calcareous shales, fragmented and fossiliferous dolomitic limestone, and calcarenites (TN&A, 2001).

The site is considered to be located in an area relatively free of earthquake activity.

3.5 HYDROGEOLOGY

3.5.1 Regional Hydrogeology

There are four principal aquifers in the Des Moines County area: a glacial drift aquifer, and three bedrock aquifers of the Mississippian, Devonian, and Cambro-Ordovician units. The uppermost aquifer is a discontinuous surficial aquifer comprised of unconsolidated loess and glacial till, with thin fluvial Pleistocene age deposits within the streambeds. These occupy the upland till terrace and are predominately clayey glacial tills exhibiting low hydraulic conductivities that yield small quantities of groundwater to wells.

Depth to groundwater in the drift aquifer (loess/till) is generally less than 10 ft, and shallow groundwater flows parallel to surface topography. Groundwater discharges to the more deeply incised surface drainage streams with additional discharge downward to deeper drift sections and to the bedrock aquifer; however, this downward flow is restricted by the low permeability of the drift. Recharge is slow to the drift aquifer and is derived from precipitation infiltration and inflow from adjacent areas as well.

3.5.2 Site Hydrogeology

There are two main aquifers affected by operations at the IAAAP: the drift aquifer (loess/till) and the underlying upper bedrock aquifer. The drift aquifer, where the majority of contaminant movement likely occurs, is comprised of shallow, confined sandy silt/silty sand deposits in the floodplain and adjacent till terraces of Brush Creek. Groundwater flow in the drift aquifer in the area of Line 1 generally converges toward Brush Creek from the eastern terrace and uplands areas. The bedrock interface is structurally controlled by secondary porosity consisting mostly of voids along bedding planes. Groundwater flow in the bedrock aquifer is generally planar along the bedrock dip which is reported to trend southeast (TN&A, 2001).

The groundwater surface in the drift aquifer across the IAAAP roughly occurs within 10 ft below ground surface. Shallow groundwater flow nearly parallels the ground surface. Thus, shallow groundwater throughout the installation flows from the higher elevation points, including most of the Line 1 and yard areas, toward surface drainages areas, including the unnamed tributaries feeding Spring, Brush, and Long Creeks as well as Skunk River. The water in the upper bedrock aquifer generally flows to the south and east, toward the Skunk and Mississippi Rivers. In some on-site areas, including the southwestern portion of the IAAAP, the upper bedrock aquifer is exposed at ground surface and discharges into surface waters. In other areas of the site, the upper bedrock aquifer lies at depths of more than 50 to 100 ft (USACE, 2001).

The Kellerville Till is distinguished from older pre-Illinoian till by its high dolomite and illite content which tends to harden due to the mineral matter filling the interstitial spaces. This hardened mineral matter reduces the porosity of the till. Laboratory analysis of an undisturbed sample (monitoring well JAW-51) of the till collected via Shelby tube at a depth of 19.5 to 21.5 ft below ground surface determined the till has a vertical hydraulic conductivity of 5.8×10^{-9} centimeters per second (cm/s). A slug test of the aquifer was performed near Line 1 (well G-14) that estimated the horizontal hydraulic conductivity to be 8.5×10^{-4} cm/s. In general, groundwater in tills flows horizontally through higher hydraulically conductive zones in near-surface units with low vertical hydraulic conductivity (USACE, 2001).

3.6 SURFACE WATER AND SEDIMENT

3.6.1 Surface Water

Most of the surface water across the IAAAP is drained by three major streams (Brush Creek, Long Creek, and Spring Creek) that divide the facility into four drainage basins trending northwest to southeast. There is also an unnamed tributary that drains the southwestern portion of the IAAAP and discharges into Skunk River, and Little Flint Creek which drains a small portion of the northern area of the site. There are thirty ponds and small surface water impoundments across the IAAAP site. There are several sloped areas and storm water drainage ditches that convey storm water runoff and eventually discharge into Brush Creek. Long Creek drains the western portion of the facility, flowing into Mathes Lake and exiting the site along the southern boundary where it discharges into Skunk River, which ultimately discharges into the Mississippi River. Brush Creek drains the central portion of the site and Spring Creek drains the eastern portion of the site. Both creeks exit the site toward the southeastern boundary and continue to flow southeasterly for approximately four miles where they discharge into the Mississippi River.

3.6.2 Sediment

For the purposes of this RI, sediment was considered to be that soil-like material that exists in association with existing streams and drainage ways. This material includes depositional soil areas adjacent to such drainages as well as saturated soil material within or adjacent to waterways. At IAAAP, such sediments typically consist of silty sands.

3.7 ECOLOGY

Potential source areas for contamination are located within the watersheds, with some draining into more than one watershed. The habitats around these areas are variable. Forest, agricultural land, ruderal areas, and other habitats suitable for terrestrial and aquatic receptors exist throughout IAAAP (TN&A, 2002).

3.7.1 Terrestrial Habitats

IAAAP is separated by large areas of terrestrial habitat. Within the potential source areas themselves, there are also large areas of terrestrial habitat. The terrestrial habitats are composed of temperate deciduous forests, prairies, industrial and ruderal areas, and agricultural croplands. Forest types can be separated into floodplain and upland forests, with the former predominating. Agricultural uses include row crops, corn and soybeans, and pasture for beef production (TN&A, 2002). Receptors include small mammals and vertebrates.

3.7.2 Aquatic Habitats

The aquatic habitats include sections of Long Creek, Brush Creek, and Spring Creek that flow within IAAAP, along with any related tributaries and tributaries to the Skunk River. Because of IAAAP's large size, some of the headwaters of these streams and tributaries originate within the boundaries of IAAAP. These streams primarily flow through deciduous forests and deciduous wetland swamps, and are removed some distance from the potential source areas. These streams provide a habitat for a variety of aquatic receptors. Receptors include fish, benthic invertebrates, and amphibians. The streams and tributaries are a source of food and water for wildlife and avian species (TN&A, 2002).

3.7.3 Threatened and Endangered Species

A Baseline Ecological Risk Assessment (BERA) (USACE-Omaha, 2004) was performed at the IAAAP in 2004. According to the BERA, two federal-listed threatened or endangered species have been recorded on the IAAAP property. The bald eagle *(Haliaeetus leucocephalus),* listed as threatened, has been recorded to feed at Mathes Lake. Indiana bats *(Myotis sodalis)* have also been recorded to feed on the property, and may have maternal roosts in the floodplain forests. The BERA also presents state-listed endangered, threatened, and special concern species observed at the IAAAP, which are presented below.

Plants - Threatened

- Virginia snakeroot *(Aristolochia serpentaria)*
- Downy wood-mint *(Blephilia ciliate)*
- Blue ash *(Fraxinus quadrangulata)*
- Sharpwing monkeyflower *(Mimulus alatus)*
- Slender ladies tresses *(Spiranthes lacera)*
- False hellebore *(Veratrum woodi)*

Plants – Special Concern

- Ragged fringed orchid *(Platanthera lacera)*

Animals - Threatened

- Orangethroat darter *(Etheostoma spectabile)*

The orangethroat darter *(Etheostoma spectabile)* is common in Spring and Brush Creeks and is considered a threatened species in Iowa. According to the BERA, several threatened plants were found in the upland or floodplain forests.

4.0 NATURE AND EXTENT OF CONTAMINATION

This section presents the nature and extent of the PCOCs, as identified within the RIWP (USACE, 2007), for each investigation area or sub-area, described in Section 1.2 as being within the scope of this document. The determination of the nature and extent of the identified PCOCs builds upon the previously-conducted environmental investigations and utilizes the data obtained during the FUSRAP 2006-2007 remedial investigation to augment and/or supplement the previously-obtained data.

Individual analytes for each investigation area were evaluated using the following stepwise approach:

- Analytes with no single point that exceeded the PRG (or surrogate PRG) were not carried forward for further evaluation for that area;
- Analytes with no established PRG and no detectable concentrations were not carried forward for further evaluation for that area;
- Analytes without an established PRG that exhibited detectable concentrations were further evaluated to determine if they were essential nutrients (calcium, magnesium, potassium, sodium, etc.). If it was determined that they were essential nutrients, the analyte was not carried forward for further evaluation for that area.
- An area Exposure Point Concentration (EPC) was then calculated for each remaining analyte. If the EPC for the area did not exceed the applicable PRG, the analyte was not carried forward for further evaluation for that area.
- All remaining analytes were retained for site specific risk analysis in Section 6 of this report.
- EPCs for metals determined to be risk driver COCs in the HHRA (Section 6) were evaluated directly against EPCs calculated for background to determine if some or all of the site risk can be attributed to background conditions at the IAAAP.

Data from previous investigations performed on behalf of AEC were reviewed for use in this RI Report. Among the reviewed data were the Firing Sites data collected by JAYCOR from 1992-1995 that were included in the *Iowa Army Ammunition Plant, Revised Draft Final Remedial Investigation Report/Risk Assessment* (US-Army Environmental Center, 1996). Of the sites being investigated during the FUSRAP 2006-2007 RI, only the Firing Sites were investigated by JAYCOR. However, during development of the RIWP (USACE, 2007), no defensible evidence could be found that shows that the JAYCOR RI sampling locations were surveyed or that the RI data were validated. Proof of validation, along with the appropriate applied validation qualifications is necessary in terms of designating usability of data for meeting project objectives (i.e., site contaminant and risk characterizations). Additionally, the age of the JAYCOR data suggests that the Firing Sites data may not be adequately representative of current conditions for site characterization and risk assessment purposes due to the possibility of fate and transport process that likely have occurred over the years. This is especially true when considering that operational activities have continued at the Firing Sites since collection of the JAYCOR RI data. Therefore, the JAYCOR data was used primarily to guide the establishment of new sample locations during the 2006-2007 FUSRAP RI for identifying PCOCs and determining the nature and extent PCOCs at the Firing Sites. Of primary significance in establishing new sampling locations were those JAYCOR locations with significant detections, along with biased sample locations (e.g., operational points, building entrances, and drainage ways). The JAYCOR data was not, however, used in statistical evaluations of the various parameters. The summary tables and subsequent EPC calculations do not include JAYCOR data.

Supplemental RI data collected by TN & Associates and included in the *Line 1 and Firing Site Supplemental Remedial Investigation Report, Iowa Army Ammunition Plant, Middletown, Iowa* (TN&A, 2002), are used along with sampling and analysis performed during the FUSRAP 2006-2007 investigation to verify and/or confirm existing JAYCOR RI sample locations and results. Samples taken during the FUSRAP 2006-2007 investigation have a naming convention that starts with the letters IAAP and then follows with five or six numbers (e.g. IAAP96848) Samples taken by TN&A or JAYCOR start with FS or TFS and then are followed with a set of numbers (e.g. FS01001).

4.1 DATA QUALITY SUMMARY OF FUSRAP RI DATA

During the FUSRAP RI, all soil samples for radiological analyses were submitted to the USACE FUSRAP Laboratory (i.e., the Primary Laboratory for radiological analyses) located near the former Hazelwood Interim Storage Site (HISS) in St. Louis, MO. Soil samples submitted for chemical analyses were sent to Test America St. Louis (i.e., the Primary Laboratory for chemical analyses). Samples analyzed by Test America St. Louis were split with the USACE QA Laboratory located in Vicksburg, MS.

In accordance with the QAPP (USACE, 2007), all radiological data generated by the USACE FUSRAP Laboratory and chemical data generated by Test America St. Louis were validated at a rate of ten percent. Data verification was performed on the remainder of all data from each laboratory not being validated. Split sample data generated by USACE's QA laboratory were verified before inclusion into the Quality Control Summary Report (QCSR) in Appendix B of this RI Report. Validations and verifications were performed electronically using the FUSRAP St. Louis Data and Environmental Information Management System (SLDEIMS), in which qualifiers denoting data usability were applied based on comparisons to acceptance criteria established for checklist items presented in the QAPP. Reason codes were also generated with each analytical result qualifier applied in SLDEIMS.

Data validation reports were written for the ten percent validation of the data from USACE FUSRAP Laboratory (HISS), but not for the validated chemical data from Test America. This is because the USACE QA Laboratory will prepare a Chemical Quality Assurance Report (CQAR) evaluating data quality of the split sample results. Additionally, data validation checklists or verification summaries for each SDG have been retained with the respective laboratory data. Therefore, the validation/verification checklists, data qualifiers and reason codes, radiological data validation reports, QCSR, and CQAR all provide adequate documentation of the evaluations performed for determining quality and usability of the FUSRAP data for meeting project DQOs. Appendix B of this report presents the QCSR (Attachment 1) and radiological data validation reports (Attachment 2). Once the CQAR has been received by USACE's QA laboratory, that document will be inserted as Attachment 3 to Appendix B of this report.

It should be noted, as discussed in the Data Quality Assessment Summary of the QCSR (Appendix B, Attachment 1), that all validated/verified data were determined to be usable, with data qualifications and reason codes being applied due to minor issues. Minor data issues resulted in the qualification of some detect and non-detect results as being estimated (J/UJ) with appropriate EPA qualification flags.

4.2 RISK-BASED SCREENING LEVELS

Risk-based screening levels were used for comparisons with site soil data to determine nature and extent of contamination in the investigated areas and as a first step in the determination of human health constituents of potential concern (COPCs) for evaluation later in the HHRA. The risk-based

screening levels are represented by the USEPA Region 9 Preliminary Remediation Goals (PRGs) derived for direct contact with soil under an industrial setting. Region 9 Industrial PRGs, which were obtained from the USEPA Region 9 PRG Tables (USEPA, 2004b), are discussed below.

4.2.1 USEPA Region 9 PRGs

The USEPA Region 9 PRGs are chemical-specific concentrations that correspond to fixed levels of risk (i.e. either a one-in-a-million [$1x10^{-6}$, 1E-06] excess cancer risk or a noncancer hazard quotient [HQ] of 1 in soil, air, or water). If a substance causes both cancer and noncancer (systemic) effects, the more stringent criteria is selected as the screening level (i.e., PRG). As a conservative measure, when an HQ is utilized as the screening value, it will be evaluated at one-tenth (0.1) its concentration to account for potential cumulative effects. Complete exposure pathways included for industrial use PRG calculations include ingestion, inhalation of particulates, inhalation of volatiles, and dermal absorption of chemicals in soil.

Most USEPA Region 9 PRGs are derived using standard equations; however, some PRGs are derived with special considerations. For instance, the PRG for cadmium is based on the oral reference dose (RfD) for water which is slightly more conservative (by a factor of 2) than the RfD for food. The RfD for food could be more applicable for soil exposures but the PRG based on water consumption was selected to be conservative. The PRG for total chromium assumes a 1:6 ratio of hexavalent chromium to trivalent chromium. Once again, this is a conservative assumption given the natural abundances of these two valence states. When USEPA Region 9 first published the PRG table, there were some discrepancies between California EPA (Cal-EPA) and USEPA regarding toxicities values, with the Cal-EPA values being the significantly more conservative than the risk-based PRGs calculated using USEPA toxicity values. Since the Cal-Modified PRGs are more stringent than the federal numbers, Cal-Modified PRGs are used when available.

For some SVOCs and inorganics of known low toxicity, USEPA Region 9 assigns a PRG value equivalent to a default, non-risk-based "ceiling limit" of 100,000 mg/kg. This ceiling limit is controversial among regulators, even among those with Region 9. However, Region 9 also presents risk-based values for some low-toxicity SVOCs and inorganics in their "Intercalc Table" if toxicity criteria are available for calculating those values.

Following performance of data comparisons using the ceiling limit PRGs, iron was the only chemical detected at concentrations in the investigated areas that exceeded 100,000 mg/kg. Subsequently, the corresponding risk-based value in Region 9's Intercalc table was reviewed and determined to be more appropriate for use in the data comparisons for iron. Therefore, the ceiling limit PRG for iron was replaced with the risk-based value in the data comparisons.

The following is an excerpt from the Region 9 Technical User's Guide explaining the use of the 100,000 mg/kg ceiling limit as a PRG for some chemicals:

"With respect to applying a "ceiling limit" for chemicals other than volatiles, it is recognized that this is not a universally accepted approach. Some within the agency argue that all values should be risk-based to allow for scaling (for example, if the risk-based PRG is set at a hazard quotient = 1.0, and the user would like to set the hazard quotient to 0.1 to take into account multiple chemicals, then this is as simple as multiplying the risk-based PRG by 1/10th). If scaling is necessary, PRG users can do this simply by referring to the "InterCalc Tables" at our website where risk-based soil concentrations are presented for all chemicals (see soil calculations, "combined" pathways column).

In spite of the fact that applying a ceiling limit is not a universally accepted approach, we have opted to continue applying a "max" soil concentration to the PRG Table for the following reasons:

1) Risk-based PRGs for some chemicals in soil exceed unity (>1,000,000 mg/kg), which is not possible.
2) The ceiling limit of 100,000 mg/kg is equivalent to a chemical representing 10% by weight of the soil sample. At this contaminant concentration (and higher), the assumptions for soil contact may be violated (for example, soil adherence and windborne dispersion assumptions) due to the presence of the foreign substance itself.

   PRGs currently do not address short-term exposures (e.g. pica children and construction workers). Although extremely high soil PRGs are likely to represent relatively non-toxic chemicals, such high values may not be justified if in fact more toxicological data were available for evaluating short-term and/or acute exposures.

None of the above USEPA Region 9 concerns pertain to the use of the risk-based Intercalc value for iron, as addressed in the following items:

1) The exceedance of unity (i.e., >1,000,000 mg/kg), is not a concern for the Intercalc risk-based value for iron, which is 310,000 mg/kg.
2) Soil (dermal) contact assumptions are not violated by application of the risk-based value for iron, because the exposure route basis for this value is only ingestion.
3) The exposure assumptions used for the industrial-based value of 310,000 mg/kg reflect those used in the FUSRAP RI BRA and would be protective of both the industrial (site) worker and construction worker.

4.2.2 Radiological Screening Levels

The established screening levels for total gross alpha and beta activity were selected from Table 1, Screening Levels for Clearance, American National Standards Institute (ANSI)/Health Physics Society (HPS) N13.12-1999. The screening levels for gross alpha and beta removable activity were set at 10% of the limit for total alpha and beta activity, respectively. The screening levels used for the radiological survey of structures during this RI are provided in Table 4-1

Table 4-1. Selected Screening Levels for Radiological Surveys of Structures

Screening Parameter	Total Contamination dpm/100cm^2	Removable Contamination dpm/100cm^2	Investigation Level for Scanning
Gross alpha	600	60	N/A
Gross beta	6,000	600	4,800

In many instances, the establishment of a radiological screening level is limited by the ability to detect COPCs using reasonable detection methodologies. NUREG 1507, Minimum Detectable Concentrations with Typical Radiation Survey Instruments for Various Contaminants and Field Conditions (NRC, 1998) lists the minimum detectable concentration (MDC) for scanning with a 2" x 2" sodium iodide (NaI) detector for soil contaminated with DU at 56 pCi/g. It has been determined that this level of contamination will be detected at least 95% of the time by the average survey technician walking at a rate of 0.5 meters per second (m/sec).

The 56 pCi/g screening level for DU was agreed upon during the TPP meeting held in Des Moines, IA (June 22 – 24, 2005), with concurrence from IDPH. Conservative risk and dose assessment calculations were performed using the residual radiation code (RESRAD) 6.0 to model a residential scenario with DU soil contamination at 56 pCi/g. The resulting risk and dose to the maximum

exposed individual from this evaluation is 5 x 10-5 and 8 millirem per year (mrem/yr), respectively. The corresponding dose is less than EPA's dose limit of 15 mrem/yr.

4.3 FIRING SITES AREA

4.3.1 FS-1 and FS-2

In accordance with the RI Work Plan (USACE, 2007), soils in FS-1 and FS-2 Area were investigated for metals constituents associated with previous use of the area as an X-ray film processing facility. In addition, as described below, soil sampling for DU and structure radiological surveys were also performed at the FS-1 and FS-2 Area.

4.3.1.1 Radiological

4.3.1.1.1 GWS and Soil Sampling

Survey personnel set up a temporary equipment staging area in the parking lot for FS-1 and FS-2 to support gamma walkover surveys being conducted throughout the Firing Sites. Gamma radiation walkover surveys (GWS) were not originally planned for the FS-1 and FS-2 Area. However, while returning to the temporary equipment staging area at the FS-1 and FS-2 lot, survey personnel detected a small area of elevated radiological activity along the driveway leading into the parking area. A biased surface sample (IAAP96848) was obtained from the area exhibiting elevated radiological activity. Analysis of this sample yielded a DU result of approximately 2,400 pCi/g. In addition, soil samples (IAAP100146 – IAAP100152) were subsequently obtained in the immediate area of IAAP96848 in an effort to establish the horizontal and vertical extent of the DU. Results of these samples showed that the DU identified in sample IAAP96848 is limited to an area of approximately 1 m^2 and is limited to the top foot of soil. The GWS results are shown on Figure 4-1 and data for all samples analyzed for DU from FS-1 and FS-2 are shown in Table 4-2.

As a result of the identification of elevated radiological activity at sample location IAAP96848, GWS of the FS-1 and FS-2 Area were performed. The surveys were concentrated around the FS-1 and FS-2 buildings, near drain discharge points, localized topographical low points, areas along the main FS entrance road, and areas along the driveway and parking area. The surveys indicated the presence of slightly higher radiological activity near the FS-2 building. A biased soil sample (IAAP100146) was therefore obtained along the north side of the FS-2 building, at an area representative of the slightly elevated radiological activity near the building. Analysis of sample IAAP100146 yielded DU results that are at background levels. The lack of elevated radiological constituents in the soil indicates that the slightly elevated radiological activity detected in the area near the FS-2 building was likely caused by the effects of the changed geometry when surveying immediately adjacent to the FS-2 building as well as depressed topography of a drainage swale in the immediate area.

Table 4-2. FS-1 and FS-2 Radiological Soil Sample Summary Results from the FUSRAP 2006-2007 RI

Sample ID	Sample Type		U-234 (pCi/g)	U-235 (pCi/g)	U-238 (pCi/g)
IAAP96848	Biased	ss	*	35.9	2401
IAAP100146	Biased	ss	*	0.11	0.16
IAAP100147	Biased	ss	*	-0.07	0.79
IAAP100148	Biased	ss	*	-0.09	1.08
IAAP100149	Biased	ss	*	-0.12	1.71

4.3.1.1.2 Building Surveys

Also because of the identification of DU in the FS-1 and FS-2 Area, the buildings in FS-1 and FS-2 were surveyed, following MARSSIM guidance, during the FUSRAP 2006-2007 RI. Beta scans were conducted and three fixed point readings were taken in each building. No anomalies were detected in either building and all readings were below the screening limits. Results of the FS-1 and FS-2 building surveys conducted during the FUSRAP 2006-2007 RI are presented in Table 4-3.

Table 4-3. FS-1 and FS-2 Building Survey Results for FUSRAP 2006-2007 RI

Sample ID	Sample Location	Removable Alpha (dpm/100cm^2)	Removable Beta (dpm/100cm^2)	Total Alpha (dpm/100 cm^2)	Total Beta (dpm/100 cm^2)
1	FS-1 floor near north entrance	<60	<600	97	495
2	FS-1 floor near main entrance	<60	<600	255	1674

Gross Beta Screening Level: Total = 6000 dpm/100cm^2, Removable = 600 dpm/100cm^2

4.3.1.2 Chemical

4.3.1.2.1 Metals

To investigate soils for metals associated with previous photo processing operations, seven surface soil sample locations (IAAP96841 – IAAP96847) were sampled in FS-1 and FS-2 and analyzed for metals. Figure 4-2 shows FUSRAP 2006-2007 RI sample locations as well as the locations from the previous RIs (FS01001 – FS01003, FS01005, FS01007, FS01009, FS02001, and TFS02003) for the FS-1 and FS-2 area. Sample locations were established near the FS-1 and FS-2 buildings, near doorways, drainage points, and localized topographical low points. In addition, a subsurface soil sample (IAAP96840) was collected from the 4-6 ft bgs interval in the location of the former septic tank leach field east of the main FS entrance road. The results of the metals analyses are summarized in Table 4-4. There were no metals results from the FS-1 and FS-2 Area that exceeded the PRGs.

Although EPA Region 9 has established PRGs for aluminum and iron, these metals do not appear on U.S. EPA's 2007 CERCLA Priority List of Hazardous Substances and are therefore, technically not subject to response under CERCLA, unless they clearly represent an imminent and substantial danger to public health so as to meet the definition of "pollutant or contaminant" under 40 CFR 300.5.

4.3.1.3 FS-1 and FS-2 Summary

Based on the historical evaluation, previously collected data, fieldwork associated with the FUSRAP 2006-2007 RI, and the data presented in the preceding text, there are no PRG exceedances associated with metals in FS-1 and FS-2 Area. DU was found to be present at a level greater than the screening level of 56 pCi/g at one isolated area along the entrance driveway that leads to the parking lot between the FS-1 and FS-2 buildings. Additional evaluation of this data is warranted to determine risk levels as well as the potential for future actions.

4.3.2 FS-3, FS-4, and FS-5

In accordance with the RI Work Plan (USACE, 2007), the soils in the area of FS-3, FS-4, and FS-5 were investigated for potential contaminants that may have resulted from the previous use of the area and associated buildings for munitions storage and other operations. These potential contaminants included metals, explosives, and DU. Findings of these investigations are described below.

4.3.2.1 Radiological

4.3.2.1.1 GWS and Soil Sampling

Gamma radiation walkover surveys were conducted at FS-3, FS-4, and FS-5 during the FUSRAP 2006-2007 RI field efforts. These surveys concentrated around buildings near loading docks, drain discharge points, localized topographical low points, roadsides, and along driveways and parking areas. Gamma walkover survey results are shown on Figure 4-3. The gamma radiation levels found in this area were within the range of expected background and exhibited normal fluctuations due to factors such as cover material and topography with one exception. One isolated area of elevated radiological activity was identified immediately adjacent to the loading dock at FS-5. Further

investigation identified the presence of an apparent DU object, approximately 4-5 in. diameter, approximately 3-4 in. below the ground surface. Soil beneath the object showed the presence of yellow oxidation products and significantly elevated radiological counts. Three surface soil samples (IAAP100161, IAAP100162, and IAAP100163) were obtained approximately two meters to the north, west, and south, respectively, of the DU object in an effort to bound the area of soil contamination associated with the object. Data for all samples analyzed for DU from FS-3, FS-4 and FS-5 are shown in Table 4-5. (The FS-5 building is located approximately 1 foot east of the location where the object was found, therefore additional sampling to the east was not necessary.) An effort was made to obtain a sample from the soil interval beneath the object but the presence of a layer of apparent asphalt, possibly from a previous driveway, prevented the collection of such a sample. Analyses of IAAP100161, IAAP100162, and IAAP100163 yielded DU results that were below the screening criteria of 56 pCi/g, indicating that the area affected by the DU object is limited to the immediate area (approximately 2 m^2) around the object itself. The DU object and associated soil were left in place. After finding the DU object an additional five surface soil samples (IAAP100156 – IAAP100160) were obtained from locations around the FS-5 building. No elevated DU concentrations were found in any of these five samples.

In addition to the above samples, five other soil samples (IAAP96835 – IAAP96839) were collected from the surface interval (0cm to 15cm) at locations adjacent to building structures at FS-3, FS-4, and FS-5. No elevated DU concentrations were found in any of these five samples.

4.3.2.1.2 Building Surveys

Buildings interiors at FS-3, FS-4, and FS-5 were surveyed following MARSSIM guidance during the FUSRAP 2006-2007 RI. The surveys were performed in areas where contamination would most likely be found (i.e., entrances and exits, ventilation components, sumps and floor drains, high traffic areas, and shipping and receiving loading and offloading areas). Beta scans were performed in the buildings and a total of seven fixed point alpha/beta readings and smears were taken. Two were taken in FS-3, two were taken in FS-4, and three were taken in FS-5. No readings were above the screening limits. Results of the FS-3, FS-4, and FS-5 structure surveys conducted during the FUSRAP 2006-2007 RI are presented in Table 4-6.

4.3.2.2 Chemical

4.3.2.2.1 Explosives

To investigate soils for explosives associated with previous operations, five surface soil locations (IAAP96835 – IAAP96839) were sampled in FS-3, FS-4, and FS-5 area during the FUSRAP 2006–2007 RI and analyzed for explosives. Sample locations were established near buildings, doorways, drainage points, and localized topographical low points. Figure 4-4 shows the FUSRAP 2006-2007 RI explosives sample locations as well as the seven locations for the previously-obtained samples (FS03001, FS03002, FS04001, FS04002, FS05001, FS05002, and FS05003) for the FS-3, FS-4, and FS-5 area. The results of all FS-3, FS-4, and FS-5 explosives analyses are summarized in Table 4-7. There were no explosives results from the FS-3, FS-4, and FS-5 area that exceeded the PRGs.

4.3.2.3 FS-3, FS- 4, and FS-5 Summary

Based on the historical evaluation, previously-collected data, fieldwork associated with the FUSRAP 2006-2007 RI, and the data presented in the preceding text, there are no PRG exceedances for explosives or metals in the FS-3, FS-4, and FS-5 area. An object containing DU at levels exceeding the 56 pCi/g screening level was found to be present at one isolated area immediately adjacent to the FS-5 loading dock. Additional sampling in the area of the DU object indicated that soil contamination associated with the object is limited to the immediate area (approximately $2m^2$) of the object itself. Additional evaluation of this data is warranted to determine risk levels as well as the potential for future actions.

4.3.3 FS 6, 7, 8, and 15 Area

In accordance with the RI Work Plan (USACE, 2007), the soils in the area of FS-6, FS-7, FS-8 and FS-15 were investigated for potential contaminants that may have resulted from the previous use of the area. These potential contaminants included metals, explosives, and DU. Findings of these investigations are described below.

4.3.3.1 Radiological

4.3.3.1.1 GWS and Soil Sampling

Gamma radiation walkover surveys were conducted at FS-6, FS-7, FS-8, and FS-15 during the FUSRAP 2006-2007 RI field efforts. These surveys were conducted to supplement the existing GWS data obtained in 2000. The survey conducted in 2000 focused on FS-6 at ground zero, the area surrounding ground zero, drainages from ground zero, and the adjacent FS-6 berm. The survey conducted during the FUSRAP 2006-2007 RI effort focused on FS-7, FS-8, and FS-15 and connecting roadways and ditches. The combined gamma walkover survey results are shown on Figure 4-6. During the FUSRAP 2006-2007 GWS survey one area of elevated activity was identified near the northeast corner intersection of the main FS roadway and the access road that connects FS-6 with FS-12. An isolated chunk of DU was identified covered by about 3 inches of soil. The DU chunk was removed and placed in the DU waste drum located at FS-12. Soil beneath the object showed the presence of yellow oxidation products and significantly elevated radiological counts. One soil sample (IAAP100176) was obtained from soil directly beneath and surrounding the removed DU chunk. The analytical results of soil samples collected from this area are shown in Table 4-9. The rest of the gamma radiation levels found in this area were within the range of expected background and exhibited normal fluctuations due to factors such as cover material and topography.

IAAP25000 thru IAAP25006 are soil samples obtained during the 2000 investigation of FS-6. During this previous investigation, a gamma walkover survey had identified elevated count rates in the berm of FS-6. A biased soil sample (IAAP25004) was sampled in the vicinity of the elevated count rates. During the FUSRAP 2006-2007 RI effort this area was further investigated. The previously identified count rates associated with IAAAP25004 could not be reproduced. During the FUSRAP 2006-2007 RI effort, ten biased samples (IAAP96821-IAAP96830) were collected from the surface interval (0 cm to 15 cm) in FS-7, FS-8, and FS-15 and analyzed for radiological constituents.

4.3.3.2 Chemical

4.3.3.2.1 Explosives

Analytical results from ten historical samples indicated results that did not exceed applicable PRGs, however, during the FUSRAP 2006 – 2007 RI site walk down with the FUSRAP project team, additional sample locations were deemed necessary to fully investigate the nature and extent of explosives at FS-6, FS-7, FS-8 and FS-15. To supplement existing data, ten surface (0 – 0.5 ft.) samples (IAAP96821 – IAAP96830) were collected from biased locations across the FS-6, FS-7, FS-8, and FS-15 area, collected and analyzed for explosives. Figure 4-7 shows the sample locations. The results of the explosives analyses are summarized in Table 4-10. Surface soil samples (0.0 – 0.5 ft) were collected from two locations in the concrete structure at the northern end of the area (IAAP96826 and IAAP96827), which exhibited levels of explosives (RDX and 2,4,6-TNT) above PRGs. A subsurface sample (1.0 – 2.0 ft) was later collected from location IAAP96827, to determine vertical extent of contamination, in which detected concentrations of all explosives were less than PRGs. A total of fourteen surface (0.0 – 0.5 ft) and subsurface (0.5 - 1.0 ft) samples were collected from thirteen additional locations to further delineate horizontal and vertical extent of explosives contamination at the northern end of the area, around the concrete structure. These included twelve surface soil samples from locations IAAP96849 – IAAP96857, IAAP100184, IAAP100186, and IAAP100188, and two subsurface soil samples from locations IAAP100185 and IAAP100188. All sampling results indicate that the explosive contamination on FS-6, FS-7, FS-8, and FS-15 was limited to the vicinity of the concrete structure and the immediately surrounding area to a depth of 1 foot. A total of 36 surface and subsurface soil samples collected from 32 locations were analyzed for explosives in the FS-6, FS-7, FS-8, and FS-15 area.

4.3.3.2.2 Metals

Analytical results from two historical samples indicated results that did not exceed the PRG, however, during the FUSRAP 2006 – 2007 RI site walk down with the FUSRAP project team, additional samples were deemed necessary to fully investigate the nature and extent of metals at FS-6, FS-7, FS-8 and FS-15. To supplement existing data, ten surface (0 – 0.5 ft.) samples (IAAP96821 – IAAP96830) were collected from biased locations across the FS-6, FS-7, FS-8, and FS-15 area and analyzed for metals. Figure 4-8 shows the sample locations. The results of the metals analysis are summarized in Table 4-11. Two samples (IAAP96823 and IAAP96829) indicated levels of metals above the associated PRG. Sample IAAP96829, obtained near ground zero on FS-6, indicated levels of chromium above the respective PRG. Additional surface (0.0 – 0.5 ft) samples were obtained around the original sampling location to establish the horizontal

extent of contamination. Sample IAAP96823 obtained near the target structure on FS-7 indicated levels of metals (chromium and aluminum,) above their respective PRGs. Additional surface (0.0 – 0.5 ft) samples were obtained around the original sampling location to establish the horizontal extent of contamination. The metals contamination on FS-6, FS-7, FS-8, and FS-15 was limited to the vicinity of ground zero on FS-6 and the target structure on FS-7. A total of twenty-two locations were sampled for metals in the FS-6, FS-7, FS-8, and FS-15 area. There were ten results that exceeded the PRGs. Aluminum (1) and Chromium (9) had exceedances above the PRGs.

Although EPA Region 9 has established PRGs for aluminum and iron, these metals do not appear on U.S. EPA's 2007 CERCLA Priority List of Hazardous Substances and are therefore, technically not subject to response under CERCLA, unless they clearly represent an imminent and substantial danger to public health so as to meet the definition of "pollutant or contaminant" under 40 CFR 300.5

4.3.3.3 FS 6, 7, 8, 15 Area Summary

Based on the historical evaluation, previously-collected data, fieldwork associated with the FUSRAP 2006-2007 RI, and the data presented in the preceding text, this area indicates the presence of DU, explosives, and metals above the associated PRGs. The DU appears to be limited to very small areas on the berm of FS-6 and adjacent to the concrete structure at the junction of the roadways. The explosive contamination is limited to the area in and around the concrete structure and road junction. The source of DU and explosives contamination is believed to be test firing at the concrete structure. The metals contamination is limited to the area near ground zero at FS-6 and the target structure on FS-7. The source of metals contamination is remnants of the projectiles fired FS-6 ground zero and the target structure on FS-7.

4.3.4 FS-12 Area

In accordance with the RI Work Plan (USACE, 2007), the soils in the FS-12 area were investigated for potential contaminants that may have resulted from the previous use of the area. These potential contaminants included metals, explosives, and DU. Findings of these investigations are described below.

4.3.4.1 Radiological

4.3.4.1.1 GWS and Soil Sampling

Gamma radiation walkover surveys were conducted at FS-12 area during the FUSRAP 2006-2007 RI field efforts. These surveys were conducted to supplement the existing GWS data obtained in 2000. The 2000 survey focused on FS-12 at ground zero, area surrounding ground zero and the observation bunker, the cleared area surrounding ground zero, drainages from the cleared area, and limited investigation into the surrounding trees. The previous survey had identified a high concentration of DU at ground zero with decreasing concentrations proportional to distance from ground zero. The previous survey had established that the extent of DU did not extend to the creek but did extend beyond the cleared area into the trees. The survey conducted during the FUSRAP 2006-2007 RI effort focused on attempting to establish the outer bounds of the DU contamination within the trees. The combined gamma walkover survey results are shown on Figure 4-9. An outer ring was established approximately 91 meters (100 yds) from the previously determined outer point of DU impact. This area was surveyed to determine the presence of DU. The survey coverage was limited due to the presence of the trees and associated under brush. However, numerous locations of DU were identified within the survey area. Based on the gamma walkover it appears that the extent of DU was established to the south, southwest, southeast, and east of ground zero. Survey coverage was extremely limited west of ground zero due to thick patches of briars and brush. Elevated areas were identified near the established perimeter and may extend further west. Survey coverage was better to the north and northeast of ground zero but elevated count rates were clearly identified near the perimeter and no definitive boundary of DU extent was established. Several areas of elevated activity were further investigated by hand during the investigation. Most of the investigations revealed the presence of DU chunks ranging from 1-7 inches in diameter buried from 1 – 12 inches beneath the soil. There were a few instances where a DU chunk was not found, but the presence of yellow oxidation products (DU oxidation) was observed. Since the survey had identified elevated locations near the roadways at FS-1, FS-7 and FS-5, the entire road system and ditches were surveyed (including the track connecting FS-12 with FS-7), no additional elevated locations were identified.

Thirteen soil samples were taken during the 2000 investigation, for the purpose of attempting to correlate the gamma walkover count rates with DU concentration. Rough correlation was found to be possible at higher concentrations but was entirely dependent upon the presence of DU fragments, depth of cover soil, and amount of oxidation present surrounding the fragment. Very few samples were obtained without the presence of DU fragments thus a correlation of count rate to concentration was not established.

During the FUSRAP 2006 – 2007 RI effort, to supplement existing data, eight randomly located surface (0 – 0.5 ft.) samples were collected from the FS-12 Area and analyzed for DU. The samples (IAAP100198 – IAAP100205) had results ranging from 1.19 to 34.5 pCi/g of U-238. Results are summarized in Table 4-12.

In addition, during the FUSRAP 2006 – 2007 RI effort, the cleared area of FS-12 was divided into four quadrants. An investigation trench, approximately 4 feet deep by 12 feet long was dug in each quadrant. The spoils and walls from each trench were evaluated by a geologist in 1 foot increments in an attempt to determine depth of disturbed soil, if any. In addition, each 1 foot lift of spoils was

subject to a radiological survey, soil sample, and visual inspection for the presence of DU chunks, fragments, or oxidation products.

The northwest trench (Trench #1) was excavated to a depth of four feet. A radiological survey was performed on the area of the trench prior to beginning excavation, the radiological survey indicated the elevated count rates. The first 1-foot lift of soil revealed the presence of yellow oxidation products. The soil sample (IAAP100210) confirmed the presence of DU. The following soil samples (IAAP100211 – IAAP100213) from the subsequent lifts indicated decreasing concentrations of DU consistent with the radiological scans. Undisturbed soil was encountered at approximately the 2 foot interval in Trench #1.

The southwest trench (Trench #2) was excavated to a depth of approximately four feet. No elevated counts were identified prior to or during excavation at this trench. Undisturbed soil was encountered at approximately the 2 foot interval in Trench #2. Samples obtained in this trench (IAAP100206 – IAAP100209) indicated the presence of low concentrations of DU on the surface with decreasing concentrations proportional to depth.

The northeast trench (Trench #3) was excavated to a depth of approximately four feet. No elevated counts were identified prior to or during excavation at this trench. The soil at this location did not appear to have been disturbed, no definitive demarcation of disturbance was identified. Samples obtained in this trench (IAAP100214 – IAAP100217) were comparable to background.

The southeast trench (Trench #4) was excavated to a depth of approximately four feet. No elevated counts were identified prior to or during excavation at this trench. The soil at this location did not appear to have been disturbed, no definitive demarcation of disturbance was identified. Samples obtained in this trench (IAAP100218 – IAAP100221) were comparable to background.

Photographs of the trenches are presented in Appendix E. Sample and trench locations are shown on Figure 4-9.

A total of thirty seven soil samples have been collected and analyzed for DU at FS-12. Depths of samples ranged from surface (0.0 to 0.5 ft) to subsurface (as deep as 4.0 ft). There were nine exceedances of 56 pCi/g DU.

4.3.4.1.2 Building Surveys

An investigation of the bunker at FS-12 was conducted in 2001. The investigation of the FS-12 basement bunker consisted of air sampling, total alpha measurements, total beta-gamma measurements, loose surface contamination measurements, dose rate measurements and sludge sampling. The collected field measurement data is shown in Table 4-12a. The sludge sample alpha spectroscopy analysis results for uranium isotopes are shown in Table 4-12b. Elevated activity was identified on the floor of the basement. Radiological postings labeled "Caution – Radioactive Material" and yellow/magenta ropes (rad-rope) were placed at the entrance to the basement on FS-12 to prevent unauthorized access and the spread of contamination.

Twenty measurements were obtained from random locations within the basement bunker. Total beta-gamma and alpha contamination was measured using a Ludlum 43-89 detector. Loose surface contamination was measured by swipe technique and counted for alpha and beta contamination on a Ludlum 2929 with a 43-10-1 detector. Dose rate measurements were collected with a Ludlum Model 19 μR/hr detector at one meter above the surface. One sludge sample was collected (IAAP25023). This sample was analyzed for gamma emitting isotopes using a gamma spectroscopy system and processed for alpha spectroscopy analysis to determine the isotopic concentrations of all three uranium isotopes present in DU (U-238, U-235, and U-234).

Although EPA Region 9 has established PRGs for aluminum and iron, these metals do not appear on U.S. EPA's 2007 CERCLA Priority List of Hazardous Substances and are therefore, technically not subject to response under CERCLA, unless they clearly represent an imminent and substantial danger to public health so as to meet the definition of "pollutant or contaminant" under 40 CFR 300.5

4.3.4.2.3 PCBs

During the FUSRAP 2006-2007 RI effort, no samples were collected for PCBs. Based on historical information and previous investigation results, PCBs were not considered a contaminant of concern for FS-12 area. Figure 4-12 shows the FS 12 sample locations. The results of the historical sample analysis are summarized in Table 4-15. There were no results that exceeded the PRGs.

4.3.4.3 FS 12 Area Summary

Based on the historical evaluation, previously-collected data, fieldwork associated with the FUSRAP 2006-2007 RI, and the data presented in the preceding text, there are no PRG exceedances for explosives, metals, or PCBs in the FS-12 area. UXO support during the investigation in 2000 identified the presence of explosive chunks on the surface of FS-12. However, at the time of sampling no explosive chunks were identified. DU is present on FS-12, well above background values. The extent of DU at the FS-12 area extends at least well over 100 meters in all directions from ground zero. The extent appears to be limited by the gamma walkover to the south and southeast at about 150 meters. The extent of DU extends beyond 160 meters in all other directions. The presence of DU was identified in the sludge of the bunker basement present on FS-12.

4.3.5 FS-14

In accordance with the RI Work Plan (USACE, 2007), the soils in the area of FS-14 were investigated for potential contaminants that may have resulted from the previous use of the area and associated buildings for munitions operations. These potential contaminants included metals, explosives, and DU. Findings of these investigations are described below.

4.3.5.1 Radiological

4.3.5.1.1 GWS and Soil Sampling

Gamma radiation walkover surveys were conducted at the FS-14 Area during the FUSRAP 2006-2007 RI field efforts. These surveys concentrated around buildings, near drain discharge points, localized topographical low points, roadsides, and along driveways and parking areas. In addition, GWS was also performed in the cleared field and fire-break areas to north and northeast of the FS-14 buildings and parking area. Gamma walkover survey results are shown on Figure 4-13. There were no areas that exhibited radioactivity above the surrounding areas. In addition to the GWS, four soil samples were collected from the surface interval (0 ft to 0.5 ft) from locations selected to represent soil areas adjacent to FS-14 structures, test pads, and topographical low points. Analysis of these samples show that no sample contained DU in excess of 56 pCi/g. Data for these four samples are shown in Table 4-16.

Table 4-16. FS-14 Radiological Soil Sample Summary Results from the FUSRAP 2006-2007 RI

4.3.5.2 Chemical

4.3.5.2.1 Explosives

To investigate soils for explosives associated with previous operations, nine surface soil locations (IAAP96831 – IAAP96834 and IAAP100193 – IAAP100197) were sampled in the FS-14 area during the FUSRAP 2006–2007 RI. Sample locations were established near FS-14 buildings, doorways, drainage points, driveways, and localized topographical low points. Figure 4-14 shows the FUSRAP 2006-2007 RI explosives sample locations as well as the seven locations for the previously-obtained samples (FS14001 – FS14005, FS14008, and FS14009) for the FS-14 area. Results of all explosives samples obtained from FS-14 are summarized in Table 4-17. There were no results that exceeded the PRGs.

4.3.5.2.2 Metals

To investigate soils for metals associated with previous operations, nine surface soil sample locations (IAAP96831 – IAAP96834 and IAAP100193 – IAAP100197) were sampled in the FS-14 area during the FUSRAP 2006–2007 RI. Sample locations were established near FS-14 buildings, doorways, drainage points, driveways, and localized topographical low points. Figure 4-15 shows these FUSRAP 2006-2007 RI explosives sample locations as well as the three locations for the previously-obtained samples (FS14001 – FS14007) for the FS-14 area. Results of all metals samples obtained from FS-14 are summarized in Table 4-18. There were no results that exceeded the PRGs.

4.3.5.3 FS-14 Summary

Based on the historical evaluation, previously-collected data, fieldwork associated with the FUSRAP 2006-2007 RI, and the data presented in the preceding text, there are no PRG exceedances for DU, explosives or metals in the FS-14 area.

4.3.6 Downgradient Sediment Sampling at Firing Sites Area

In accordance with the Work Plan (USACE, 2007) eight sediment samples (IAAP100153 – IAAP100155, IAAP100164, IAAP100165, IAAP100178, IAAP100180, and IAAP100187) were obtained from the surface (0 ft. to 0.5 ft.) from depositional areas along Long Creek and its tributaries in order to assess the possibility of migration of potential contaminants within the Firing Sites Area. These potential contaminants included metals, explosives, and DU. These samples are shown on Figures 4-3 through 4-11, depending on which area of the Firing Sites in which they are located. Findings of these investigations are described below.

4.3.6.1 Radiological

Eight sediment samples were collected from the surface interval (0 ft to 0.5 ft) from locations selected to represent depositional areas adjacent to Long Creek and its tributaries. Analysis of these samples show that no sample contained DU in excess of 56 pCi/g screening level. Data for these eight samples are shown in Table 4-19.

4.3.6.4 Downgradient Sampling at Firing Sites Area Summary

Sediment from depositional areas along streams downgradient from the active and formerly-used areas of the Firing Sites was sampled and analyzed for DU, explosives, and metals. This data yielded no results greater than PRGs and indicates that surface migration or transport of DU, explosives, or metals from the Firing Sites is not occurring to any significant extent.

4.4 WAREHOUSE 3-01

The interior of Warehouse 3-01 was identified and defined within the *Preliminary Assessment: Iowa Army Ammunition Plant, Middletown, Iowa* (PA) (USACE, 2001a) as warranting further investigation for potential radioactive contamination under the FUSRAP. Field work was conducted in the summers of 2004 and 2005. No chemical analysis or soil sampling was completed for Warehouse 3-01 as chemicals were not potential contaminants of concern. A building interior radiological survey was conducted. Warehouse 3-01 was found to be unimpacted by radioactive contaminants. Results of the surveys were reported in Appendix A of the *Remedial Investigation Work Plan For Line 1, Firing Sites Area, Yard C, G, and L, Warehouse 3-01, and The West Burn Pads Area South of the Road* (USACE, 2007).

4.5 YARD G

Yard G was identified and defined within the *Preliminary Assessment: Iowa Army Ammunition Plant, Middletown, Iowa* (PA) (USACE, 2001a) as warranting further investigation for potential radioactive contamination under the FUSRAP. In addition, because of the use of Yard G igloos for storage of raw and finished products, the RI Work Plan (USACE, 2007) also specified that Yard G soil be evaluated for potential explosives and metals contamination.

4.5.1 Radiological

4.5.1.1 GWS and Soil sampling

Field work to investigate soils for potential DU contamination was conducted in the summers of 2004 and 2005. This investigation consisted of performing gamma radiation walkover surveys and soil sampling. Yard G soils were found to be unimpacted by radiological contamination. Results of the gamma radiation walkover surveys and soil sampling for DU were reported in Appendix A of the *Remedial Investigation Work Plan For Line 1, Firing Sites Area, Yard C, G, and L, Warehouse 3-01, and The West Burn Pads Area South of the Road* (USACE, 2007).

4.5.1.2 Building Surveys

Storage igloos within Yard G were surveyed following MARSSIM guidance during the FUSRAP 2006-2007 RI. In accordance with the RI Work Plan (USACE, 2007), radiological evaluation of the

storage igloos began with exterior surveys around each igloo drain discharge point. Exterior surveys consisted of beta scans around igloo drains and fixed point measurements taken at igloo drains. Results of Yard G exterior igloo surveys are presented in Table 4-22a. If the beta scan or fixed point measurement indicated results above the screening limits additional interior surveys would have been required as described in the RI Work Plan (USACE, 2007). No readings were above the screening limits.

In accordance with the RI Work Plan (USACE, 2007), interiors of Yard G buildings were surveyed following MARSSIM guidance during the FUSRAP 2006-2007 RI. The interiors of seven randomly-selected storage igloos (Igloos G2, G7, G16, G20, G21, G22, and G24) were surveyed. The surveys were performed in areas where contamination would most likely be found (i.e., igloo entrances/exits, ventilation components, floors, floor drains, and loading/offloading areas). Beta scans were performed in the igloos and at least three fixed point readings and smears were taken in each igloo. No readings were above the screening limits. Results of the Yard G building interior surveys conducted during the FUSRAP 2006-2007 RI are presented in Table 4-22b.

Table 4-22b. Yard G Building Interior Survey Results from the FUSRAP 2006-2007 RI

Sample ID	Sample Location	Removable Alpha (dpm/100cm^2)	Removable Beta (dpm/100cm^2)	Total Alpha (dpm/100cm^2)	Total Beta (dpm/100cm^2)
1	G2 Stained area against front wall 4' from door	<60	<600	52	1337

Gross Alpha Screening Level: Total = 600 dpm/100cm^2, Removable = 60 dpm/100cm^2
Gross Beta Screening Level: Total =6000 dpm/100cm^2, Removable = 600 dpm/100cm^2

4.5.2 Chemical

4.5.2.1 Explosives

Thirteen samples from twelve biased locations within Yard G were analyzed for explosives. The sample locations were established in soil areas near randomly-selected Yard G storage igloos and were biased towards areas near igloo drain discharge points, localized topographical low points, drainage swales, and areas immediately adjacent to the igloo loading docks. Figure 4-16 shows the Yard G sample locations. The results of the explosives analyses are summarized in Table 4-23. There were no explosive results that exceeded the PRGs.

Although EPA Region 9 has established PRGs for aluminum and iron, these metals do not appear on U.S. EPA's 2007 CERCLA Priority List of Hazardous Substances and are therefore, technically not subject to response under CERCLA, unless they clearly represent an imminent and substantial danger to public health so as to meet the definition of "pollutant or contaminant" under 40 CFR 300.5

4.5.3 Yard G Summary

Based on the historical evaluation of Yard G, the results of the gamma radiation walkover survey and associated radiological soil sampling (described fully in Appendix A of USACE, 2007), chemical analysis of soil samples, the findings during radiological scans of the storage igloos, and the data presented in the preceding text, there are no screening level exceedances for DU, explosives, or metals in Yard G.

4.6 YARD C

Yard C was identified and defined within the *Preliminary Assessment: Iowa Army Ammunition Plant, Middletown, Iowa* (PA) (USACE, 2001a) as warranting further investigation for potential radioactive contamination under the FUSRAP. In addition, because of the use of Yard C igloos for

storage of raw and finished products, the RI Work Plan (USACE, 2007) also specified that Yard C soil be evaluated for potential explosives, metals. The possibility of PCB contamination near an electrical transformer station was also investigated by analyzing a soil sample from the station for PCBs.

4.6.1 Radiological

4.6.1.1 GWS and Soil Sampling

Field work to investigate Yard C soils for potential DU contamination was conducted in the summers of 2004 and 2005. This investigation consisted of performing gamma radiation walkover surveys and soil sampling. Yard C soils were found to be unimpacted by radiological contamination. Results of the gamma radiation walkover surveys and soil sampling were reported in Appendix A of the *Remedial Investigation Work Plan For Line 1, Firing Sites Area, Yard C, G, and L, Warehouse 3-01, and The West Burn Pads Area South of the Road* (USACE, 2007).

4.6.1.2 Building Surveys

Storage igloos within Yard C were surveyed following MARSSIM guidance during the FUSRAP 2006-2007 RI. In accordance with the RI Work Plan (USACE, 2007), radiological evaluation of the storage igloos began with exterior surveys around each igloo drain discharge point. Furthermore, the work plan specified that interior surveys would be performed in igloos where exterior survey results indicated possible elevated radioactivity. The exterior surveys of four igloos (C27, C28, C30, and C34) yielded readings slightly above the investigation levels. Therefore, these four igloos underwent additional survey (consisting of subsequent exterior re-survey of C27, C28, C30, and C34, as well as surveys of the interior). No readings were above the screening limits. Results of Yard C exterior igloo surveys are presented in Table 4-25a.

4.6.2 Chemical

4.6.2.1 Explosives

Twenty six samples from twenty four biased locations within Yard C were analyzed for explosives. Sample locations were biased to focus on soil areas adjacent to igloos and associated loading docks as well as potential contaminant accumulation areas such as ditches that drain igloo areas and related railroad lines. The sample locations that were analyzed for explosives are shown on Figure 4-18. Results are summarized in Table 4-26. There were no results that exceeded the PRGs.

4.6.2.2 Metals

Twenty one samples from twenty biased locations within Yard C were analyzed for metals. These sample locations were biased to focus on soil areas adjacent to igloos and associated loading docks as well as potential contaminant accumulation areas such as ditches that drain igloo areas and related railroad lines. The twenty sample locations that were analyzed for metals are shown on Figure 4-19. Results are summarized in Table 4-27. There were no results that exceeded the PRGs.

Although EPA Region 9 has established PRGs for aluminum and iron, these metals do not appear on U.S. EPA's 2007 CERCLA Priority List of Hazardous Substances and are therefore, technically not subject to response under CERCLA, unless they clearly represent an imminent and substantial danger to public health so as to meet the definition of "pollutant or contaminant" under 40 CFR 300.5

4.6.2.3 PCBs

One sample (IAAP96899) was taken in Yard C near electrical transformers. This sample location is shown on Figure 4-20. Results are summarized in Table 4-28. No PCB results exceeded the PRGs.

4.6.3 Yard C Summary

Based on the historical evaluation of Yard C, the results of the gamma radiation walkover survey and associated radiological soil sampling (described fully in Appendix A of *USACE, 2007*), chemical analysis of soil samples, the findings during radiological scans of the storage igloos, and the data presented in the preceding text, there are no screening level or PRG exceedances for DU, explosives, metals, or PCBs in Yard C.

4.7 YARD L

4.7.1 Radiological

4.7.1.1 GWS and Soil sampling

Yard L was identified and defined within the *Preliminary Assessment: Iowa Army Ammunition Plant, Middletown, Iowa* (PA) (USACE, 2001a) as warranting further investigation for potential radioactive contamination under the FUSRAP. Field work was conducted in the summers of 2004 and 2005. Field work consisted of completing gamma walkover surveys and soil sampling. Yard L was found to be unimpacted by radiological contamination. Results of the surveys were reported in Appendix A of the *Remedial Investigation Work Plan For Line 1, Firing Sites Area, Yard C, G, and L, Warehouse 3-01, and The West Burn Pads Area South of the Road* (USACE, 2007).

4.7.1.2 Building Surveys

Building surveys were conducted in February 2003 to determine the radiological status of Yard L warehouse buildings L-37-1, L-37-2, and L-37-3. Yard L warehouses were found to be unimpacted by radiological contamination. Results of the surveys were reported in the *Iowa Army Ammunition Plant Site Reconnaissance Survey Report for Buildings L-37-1, L-37-2, L-37-3* (USACE, 2003).

4.7.2 Chemical

Based on historical data it was determined that there were no chemical PCOCs in Yard L. Therefore, no chemical sampling was conducted at Yard L.

4.7.3 Yard L Summary

Based on historical data and the data obtained in previous surveys Yard L is not radiologically impacted. Sufficient data was obtained to confirm that radiation levels are below unrestricted release criteria (ANSI/HPS, N13.12-1999) and no measurements exceeded the screening levels. While there is no Final Status Survey Plan in place for this site, sufficient data was collected to be consistent with the requirements of a MARSSIM Class 3 survey.

4.8 YARD E

The U.S. Army Toxic and Hazardous Materials Agency's *Installation Assessment of Iowa Army Ammunition Plant, Report No 127* (USATHAMA, 1980) indicates that AEC had previously controlled and operated buildings E-13 and E-14 within Yard E. Therefore, a radiological survey was performed in Buildings E-13 and E-14, as well as the soil area around the buildings during the summer of 2007.

4.8.1 Radiological

4.8.1.1 GWS and Soil Sampling

Gamma walkover surveys were conducted at Yard E that were concentrated around buildings E-13 and E-14, the area between the two buildings, the associated driveways that serve these buildings, and the rail spur located immediately east of the buildings. Gamma walkover survey results are shown on Figure 4-21. There were no areas that exhibited radioactivity at levels significantly greater than those of the surrounding areas. In addition to the GWS, surface soil samples were collected from twelve random locations near buildings E-13 and E-14 and the rail spur. Data for all samples analyzed for DU from Yard E is shown in Table 4-29. No sample contained DU in excess of 56 pCi/g.

Soil Screening Level = 56pCi/g

4.8.1.2 Building Surveys

An interior structure survey was performed within buildings E-13 and E-14. The building interiors were scanned in areas where contamination would most likely be found (i.e., entrances and exits; ventilation; sumps and floor drains; high traffic areas; and shipping and receiving loading and offloading areas). Ten fixed point readings and smears (to assess removable contamination) were taken at each building. The results of the survey Yard E, Buildings E-13 and E-14 are presented in Table 4-30. No readings above the screening level were found.

Table 4-30. Yard E Building Survey Results from FUSRAP 2006-2007 RI

4.8.2 Yard E Summary

The radiological survey yielded no evidence of DU contamination in soil surrounding buildings E-13 and E-14 or within the structures themselves. Based on the historical information available for Yard E and the data generated during the implementation of the above-described radiological

survey, the portions of Yard E formerly controlled by the AEC were found to be radiologically unimpacted.

4.9 YARD F

The U.S. Army Toxic and Hazardous Materials Agency's *Installation Assessment of Iowa Army Ammunition Plant, Report No 127* (USATHAMA, 1980) indicates that AEC had previously controlled and operated Igloo F-9 in the northwest corner of Yard F. Therefore, a radiological survey was performed within Igloo F-9 as well surrounding soil areas during the summer of 2007.

4.9.1 Radiological

4.9.1.1 GWS and Soil Sampling

Gamma walkover surveys were conducted at Yard F that were concentrated around Igloo F-9 and the rail spur that serves Igloo F-9. Gamma walkover survey results are shown on Figure 4-22. There were no areas that exhibited radioactivity at levels significantly greater than those of the surrounding areas. In addition to the GWS, surface soil samples were collected from twelve random locations near F-9 and the rail spur. Data for all samples analyzed for DU from Yard F is shown in Table 4-31. No samples contained DU in excess of 56 pCi/g.

4.9.1.2 Building Surveys

The interior of Igloo F-9 was scanned in areas where contamination would most likely be found (i.e., entrances and exits; ventilation components; floor drains; and high traffic areas.). Fourteen fixed point readings and smears were taken from within Igloo F-9. The results of the Igloo F-9 radiological survey are presented in Table 4-32. No readings above the screening level were found.

4.9.2 Yard F Summary

The radiological survey yielded no evidence of DU contamination in soil surrounding Igloo F-9 or within the igloo itself. Based on the historical information available for Yard F and the data generated during the implementation of the above-described radiological survey, the portion of Yard F formerly controlled by the AEC was found to be radiologically unimpacted.

4.10 AREA WEST OF LINE 5B

The U.S. Army Toxic and Hazardous Materials Agency's *Installation Assessment of Iowa Army Ammunition Plant, Report No 127* (USATHAMA, 1980) indicates that AEC had previously controlled and operated within the Area West of Line 5B (also referred to as "the former SECOM site"). Therefore, and in accordance with the *IAAAP Radiological Survey Plan for Portions of Yard E, Yard F, and the Area West of Line 5B (USACE, 2007b),* a radiological survey was performed within existing Building 600-86 as well the surrounding soil areas during the summer of 2007.

4.10.1 Radiological

4.10.1.1 GWS and Soil Sampling

Gamma walkover surveys were conducted at the Area West of Line 5B the results of which are shown on Figure 4-23. GWS concentrated on low points (i.e., depressions and ditches), areas adjacent to roads and the driveway leading to Building 600-86, areas surrounding the building in the northeastern corner of the area, and portions of the field lying south of the building that appear in the 1969 and 1990 aerial photographs to be possible driving paths. There were no areas that exhibited radioactivity at levels significantly greater than those of surrounding areas. In addition to the GWS, samples from twelve locations were collected from the surface interval (0 ft to 0.05 ft) across the area and analyzed for DU. Data for all samples analyzed for DU from the Area West of Line 5B is shown in Table 4-33. No sample had DU in excess of 56 pCi/g.

Gross Beta Screening Level – Total =6000 dpm/100cm^2, Removable = 600 dpm/100cm^2

4.10.2 Area West of Line 5B Summary

The radiological survey yielded no evidence of DU contamination in soil surrounding Building 600-86 or within the building itself. Based on the historical information available for the Area West of Line 5B and the data generated during the implementation of the above-described radiological survey, the Area West of Line 5B was found to be radiologically unimpacted.

4.11 SUMMARY OF NATURE AND EXTENT

Soil samples from several sub-areas at the Firing Sites exhibit contaminant levels greater than applicable PRGs. These areas include:

- DU at FS-1 and FS-2,
- DU at FS-3, FS-4, and FS-5,
- DU, explosives, and metals at the FS-6, FS-7, FS-8, and FS-15 Area, and
- DU at the FS-12 area.

With the exception of the above-indicated sub-areas at the Firing Sites, no other exceedances of applicable PRGs were identified in the areas investigated during this RI. Areas carried forward for risk evaluation are therefore the FS-1 and FS-2 Area, the FS-3, FS-4, and FS-5 Area, the FS-6, FS-7, FS-8, and FS-15 Area, and the FS-12 Area. Table 4-35 presents a summary of the nature and extent for all the areas.

Table 4-35. Summary of Nature and Extent for all Areas

Area	DU	Explosives	Metals	PCBs

4.12 INVESTIGATIVE DERIVED WASTE

A minimal amount of investigative derived waste (IDW) was generated during the execution of this investigation.

Soil from sampling activities was placed in the boreholes from which it originated. Decontamination fluids were containerized at the site where such fluids were generated. All fluids were then transferred to a portable bulk container at FS-12. The small amount of IDW generated during field activities (including latex or nitrite gloves, paper towels, etc.), was bagged and placed in the FUSRAP storage area at FS-12.

IDW generated during radiological investigations was segregated and stored in the FUSRAP storage area at FS-12.

5.0 CONTAMINANT FATE AND TRANSPORT

This section presents a general discussion of how the chemical and physical properties of site constituents, as well as site media, affect the fate and transport of such constituents. In addition, a discussion of behavior of constituents found during this RI to have PRG exceedances is also presented (Section 5.2). A discussion of the fate and transport mechanisms for soil contaminants was presented in the Line 1 and Firing Sites RI Report (TN&A, 2002). The fate and transport assumptions used in that report remain applicable to the IAAAP areas and constituents that are being investigated in this FUSRAP Remedial Investigation. Therefore, Section 5.2 contains, in large part, information regarding IAAAP contaminant fate and transport that was originally published in the Line 1 and Firing Sites Remedial Investigation Report (TN&A, 2002).

Contaminants that are present in environmental media in excess of PRGs might represent threats to the health of exposed persons at the FUSRAP RI areas if the pattern and duration of contact is sufficiently great. However, the degree of impact is uncertain because of the capacity of some contaminants to move from one medium to another, or to become degraded by one or more biotic and abiotic processes. This uncertainty would be enhanced where future impacts are being projected from current or historical data-gathering activities. The extent to which each process is in operation at any given time will depend on the physical-chemical characteristics of the compound, the geophysical and geochemical characteristics of each medium, and the presence or absence of suitable microflora. The predominant soil profile at the FUSRAP RI sites is characterized by 3 to 15 ft of loess material overlying a zone of glacial till, a soil horizon that may extend in some places to a depth of 50 ft below ground surface. Consisting predominantly of clay, though with interbedded lens of sand and silt, the glacial till may present only a partial barrier to the downward movement of water soluble soil-borne contaminants.

Since the regional hydrogeology is marked by a shallow drift aquifer less than 10 feet bgs, some contaminants are likely to leach to this aquifer to some extent. This groundwater in turn is thought to outcrop to local surface water bodies and, to a limited extent, serve as a recharge to the bedrock aquifer. Taking a subset of environmentally important substances that are likely to represent the risk-drivers at the FUSRAP RI sites as a result of past or current practices, the following subsections summarize what is known about their potential to move from one medium to another or become degraded. Substances under consideration include explosives and metals (including depleted uranium). Secondary information sources used for this discussion include Agency for Toxic Substances and Disease Registry (ATSDR) Toxicological Profiles, Hazardous Substances Data Bank (SSDB) records, and the review Nitroaromatic Compounds: Environmental Effects and Screening Values (Talmage et al., 1999).

5.1 CONSTITUENT CHEMICAL AND PHYSICAL PROPERTIES

Chemical and physical properties of constituents affect their fate and transport through and among environmental media. The general chemical characteristics of a variety of constituents are summarized from published sources (USEPA 1979, Dragun 1988, Knox et al. 1993).

Mobility and persistence are two key terms used to describe the movement and partitioning of chemicals in the environment media (air, surface water, groundwater, soil, and sediment). Mobility is the potential for a chemical to migrate through a medium and persistence is a measure of how long a constituent will remain in the environment. Several physiochemical properties are typically used to predict the mobility and persistence of contaminants in media. Principal properties that influence the mobility and persistence include water solubility, vapor pressure, and carbon/water partition coefficient.

5.1.1 Water Solubility

Water solubility is the maximum concentration of a chemical that can dissolve in pure water at a given temperature and pH. Water solubility is a critical property affecting the environmental transport of a chemical. Highly soluble chemicals can be rapidly leached from contaminated soil and are generally mobile in groundwater. Chemicals that are not readily soluble in water have a tendency to adsorb to soils. The solubility of chemicals that are not readily soluble in water can be enhanced in the presence of organic solvents or under acidic conditions.

5.1.2 Vapor Pressure/Henry's Law Constant

Vapor pressure is a measure of the pressure at which a compound is in equilibrium with its vapor. The value can be used to estimate the extent to which a chemical will travel in air, as well as the rate of volatilization from soils and solution. A chemical's volatilization rate from water depends on its vapor pressure and water solubility. Highly water-soluble chemicals generally volatilize from water at lower rates than chemicals with low water solubility. While vapor pressure is a measure of the volatility of chemicals in their pure state, the Henry's Law Constant is the ratio of a chemical's vapor pressure (in atmosphere) to its solubility (in moles/cubic meter [m^3]). The Henry's Law Constant is more accurate than vapor pressure in estimating releases from water to air. Chemicals with Henry's Law Constants greater than approximately $1.0x10^{-3}$ atmosphere-cubic meters per mole (atm-m^3/mol) and molecular weights less that 200 g/mol are considered to be volatile organic compounds (e.g., VOCs) and can be expected to volatilize readily from water. Chemicals with Henry's Law Constant values less than this will volatilize only to a limited extent.

5.1.3 Carbon/Water Partition Coefficient (K_{oc})

The fate and transport of contaminants in soil are influenced by two processes that tend to bind the contaminant to the soil: adsorption and fixation. Adsorption is the process whereby dissolved ions are removed from the liquid phase and become chemically attached to the surfaces of soil particles. Positively charged metals (cations) are adsorbed to balance the negative surface charges on soil and organic matter particles. The cation exchange capacity (CEC) of the soil, the presence and relative quantity of other cations, and various other factors affect adsorption rates. The CEC of a soil is greatly influenced by the surface area of the soil particles, since ions are exchanged on the exposed mineral surfaces. Clay particles generally consists of a larger surface area, compared to sand grains, and can exchange cations within their layered structures to a greater or lesser degree depending on the clay species present. The CEC of a typical clay-rich soil may be two to 30 times higher than the CEC of a typical sandy soil (Dragun, 1988). Therefore, a soil with a high clay content can be expected to attenuate dissolved ions during transport more readily than a clay-free soil through the process of cation exchange. Fixation refers to the geochemical reactions that immobilize an element within the structure of a mineral or at the mineral surface.

Sorption processes are less complicated for organic contaminants. The affinity of a chemical for sorption on natural organic matter is expressed by its carbon/water partition coefficient (K_{oc}). A high K_{oc} indicates the compound is more likely to become fixed to organic matter within the soil matrix. Chemicals with low K_{oc} values (less than 10 milliliters per gram) are found mainly in the water phase. The amount of naturally occurring organic carbon present in a soil affects the adsorption of organic compounds in that soil. The greater the organic carbon content in the soil, the more likely it is that the organic compounds migrating through the soil will become adsorbed by the organic component of the soil. Soils with increased organic matter content generally have a higher CEC. The organic material in the soil may also sorb certain metals by other solutes through complexation reactions and cation exchange. Typically, organic matter constitutes less than 5% of a particular soil.

The distribution coefficient (K_d) is defined as the product of the K_{oc} and the fraction of organic carbon. Partitioning is used to describe the process by which a solute becomes distributed between the solid phase (sorbed to soil) and the liquid phase (groundwater). If there is a linear relation between the amount of solute sorbed and the concentration of the solute in groundwater, the K_d can be used to represent the partitioning process. Values for K_d have been compiled for many of the common contaminants encountered within groundwater under a variety of hydrogeologic settings. As K_d increases, more mass is sorbed to the solid phase and removed from solution. In general, contaminants will be sorbed more by silt and clay than sand and gravel. Site-specific values of K_d were not determined as part of this RI.

5.1.4 Persistence

Persistence is a measure of how long a chemical will exist in air, water, or soil. Phase transfer and chemical and biological degradation are major forms of removal and transformation processes. Persistence is expressed as a half-life ($t_{1/2}$), generally in days. A half-life is the period of time during which half of a given number of atoms of a specific constituent decay. After one half-life, half of the original amount of the constituent will remain. With the exception of redox reactions and CEC, inorganic contaminants (metals) are much more stable in the environment.

Degradation can occur by both chemical and biological processes. Chemical degradation can occur through such processes as hydrolysis and photolysis. Hydrolysis occurs when a water molecule (or hydroxide ion) substitutes for another atom or group of atoms present in organic compounds. Because water is plentiful in most soils, hydrolysis is an important reaction. In this reaction, a functional group, from the organic molecule is exchanged with a hydroxyl functional group from the water. One example of this reaction is the hydrolysis of chlorinated compounds, which often yields an alcohol or an alkene. This reaction is significant because typically chlorinated compounds are not readily biodegraded.

Photolysis is the degradation of dissolved organic compounds by sunlight. Light is absorbed by the compound, resulting in a chemical reaction involving molecular rearrangement, dissociation, or oxidation of the energized molecules. Indirect photolysis occurs when an organic compound reacts with other previously energized molecules, rather than directly with solar radiation. Generally, compounds in the subsurface are not significantly affected by photolysis until released into the atmosphere.

Biological degradation is the breakdown of organic compounds through biological processes. Biodegradation can occur through such processes as bioaccumulation, biotransformation or biodegradation. Biodegradation occurs most readily among organic compounds, with VOCs typically being more biodegradable than SVOCs. An example of biodegradation is the reduction of chlorinated organic compounds, which may be consumed by aerobic and anaerobic bacteria as food sources. Biodegradation may occur aerobically and/or anaerobically, depending upon the molecular structure of the chemical and the environmental conditions. Chemicals that may be completely, but slowly, degradable can be persistent in the environment over long periods of time.

Rates of degradation are available in literature but vary greatly according to the nature and conditions of the experiments used to obtain the data. Other environmental factors that may affect the mobility and persistence of contaminants include pH, concentration of other constituents in the media, soil moisture, oxidation/reduction potential, water chemistry, organic-matter content, and the presence and types of microorganisms in the subsurface.

Inorganic contaminants may undergo chemical species transformation that affects the mobility of the contaminants in the environment. For metals, the natural attenuation processes are dilution and

sorption. Dilution may occur by dispersion of dissolved contaminants in water percolating through the soil column or in groundwater. Sorption generally includes the processes of adsorption, co-precipitation, precipitation, and diffusion into the soil matrix. These are processes by which solutes become associated with the immobile, solid phase. Sorption may be either reversible or slowly reversible. Slowly reversible sorption of contaminants from solid phases exposed to un-contaminated groundwater may also contribute to dilution of the contaminant. The extent of dilution will be determined by the rate of contaminant release into solution relative to the velocity of water flow.

Most organic contaminants interact with the soil and do not move at the same rate that water does through the soil matrix. This phenomenon is referred to as retardation. Retardation is the dynamic process of adsorption to and desorption from soil materials and is specific to individual chemical compounds. In general, if a compound is strongly adsorbed, it is highly retarded. Biochemical reactions (in addition to retardation) have a major effect on the fate and transport of organic compounds.

5.2 DESCRIPTION OF CONSTITUENTS EXCEEDING PRGs

5.2.1 Explosives

Military grade RDX (containing about 10 percent cyclotetremethylene tetranitrmine (HMX) by weight) has been a widely used explosive since the early years of World War II when it began to replace or supplement TNT as the primary ingredient in shells, bombs, and detonators. A pattern of manufacturing and assembling practices has resulted in its release to the environment in some areas of the IAAAP and other military sites.

Although RDX has only low to moderate solubility in water (38.4 mg/L at 20-25^{o}C), the compound has a low absorption coefficient for soils and sediments and, thus, may migrate to the shallow groundwater at IAAAP to some extent. However, RDX has an estimated vapor pressure of 1-4 x 10^{-9} mm Hg at 25^{o}C, a low value implying that partitioning to air is unlikely. Photolysis is a potentially important process for degrading RDX in either air and/or process water (pink water), since the compound can absorb ultraviolet light strongly at wavelengths between 240 and 250 nm. In addition, biodegradation of RDX is likely to occur in soils and sediments at IAAAP, since the process has been simulated under the anaerobic conditions that are typical of clay, assuming the presence of a number of microbial isolates and mixed cultures. For example, ATSDR (1995a) reports that the process went to completion in 5 days or less in bench-top experiments. Thus, when RDX was incubated in an anaerobic test system containing sewage sludge and mixed cultures in nutrient broth, its disappearance was accompanied by the formation of a sequence of metabolites including hexahydro-1-nitroso-3,5-dintro-1,3,5-triazine (MNX), hexahydro-1,3-dinitroso-5-nitro-1,3,5-triazine (DNX), hexahydro-1,3,5-trinitroso-1,3,5-triazine (TNX), hydrazine, 1,1-dimethly-hydrazine, 1,2-dimethly-hydrazine, formaldehyde, and methanol.

TNT has a higher water solubility than RDX (130 mg/L at 20^{o}C) and consequently may be more likely than the latter compound to remain in solution in surface water bodies and less likely to partition to soils and sediments (USACHPPM, 2000). Nonetheless, large amounts of TNT have been detected in soil at this and other ammunition plants because of the large-scale production of the compound of many years. However, TNT is not expected to bioaccumulate or biomagnify in terrestrial systems.

Biotransformation in soil is an important fate and transport mechanism for TNT, since the compound is reduced by microbial action. The process appears to occur through successive reduction of the nitro groups but with conservation of the compound's aromatic ring. Bacterial

genera identified in these reactions include species of Pseudomonas, Escherichia, Bacillus, Citrobacter, Enterobacter, Lebseilla, Veillonella, and Costridium. Microbial transformation of TNT leads to a variety of reduction products, including 2-amino and 4-amino dinitrotoluene and azoxydimers, though some oxidation products have been identified also. Biological transformation by bacterial and fungal species occurs slowly in the environment, with slightly higher rates in the presence of other carbon sources.

In a manner similar to that of RDX, photolysis is another process that can affect the fate and transport of TNT in the environment. Numerous transformation products have been identified in pink water, predominantly 1,3,5-trinitrobenzene, 4,6-dinitroanthranil, 2,4,6-trinitrobezaldehyde, and 2,4,6-trinitrobenzonitrile, in addition to several azo and azoxy derivatives formed by the coupling of nitroso and hydroxylamine products.

5.2.2 Metals

Though chromium occurs naturally in the earth's crust, the element is present in the environment in large quantities as a result of mankind's activities. Electroplating, leather tanning, and textile industries are major sources of chromium release to the environment, mainly as the insoluble chromium (III) oxide. However, chromium (VI) has been detected in fly ash from coal-fired powered plants and from sites where chromium is manufactured or used.

Chromium occurring in the atmosphere as particulates will be deposited to surface water or soil as a result of wet or dry deposition. Most of the chromium in lakes and rivers will ultimately be deposited in the sediments. The majority of the chromium in soil is present as the insoluble oxide that would tend to be immobile in that matrix. However, surface runoff can transport soluble and precipitated chromium alike to surface water. ATSDR (1998) discusses at some length the potential for chromium to transition between chemical species depending on the geophysical-geochemical characteristics of the environmental matrix. For example, the fate of chromium in the soil will fluctuate depending on the redox potential and the pH of the soil. Thus, the reduction of chromium (VI) to chromium (III) is facilitated by low pH and anaerobic conditions.

Depleted uranium present at the Firing Sites is a result of "hydroshot" testing from 1965 to 1973. These explosives tests primarily produced depleted uranium fragments that settled in surface, or near-surface soils near FS-12. The DU pieces found at the Firing Sites were readily identified during gamma radiation walkover surveys. Although depleted uranium behaves in the environment in a manner similar to other metals, the particular orientation of the DU found at the firing sites, i.e., visible pieces of the metal, indicates that very little environmental transport of the depleted uranium has occurred. In addition, results of downgradient soil and sediment sampling at the Firing Sites showed no indication of DU migration from FS-12 or any other Firing Sites area (see Section 4.3.6).

Aluminum is the most common element, comprising about 8% of the earth crust. It has a solubility ranging from approximately 20 to 40 ug/L in natural waters at a nearly neutral pH, but solubility is decreased by the presence of silica, which causes precipitation as a clay mineral. At high pH, aluminum may complex with hydroxides, which may increase its mobility.

6.0 BASELINE HUMAN HEALTH RISK ASSESSMENT

This HHRA report has been prepared as part of the overall Baseline Risk Assessment (BRA) in support of the FUSRAP RI report for the IAAAP. Generally, this HHRA performs the following: 1) identifies chemical constituents of potential concern (COPCs) for quantitative risk analysis from existing lists of soil PCOCs presented in previous sections of this RI Report; and 2) calculates carcinogenic and noncarcinogenic risks for soil COPCs to determine those COPCs that predominantly contribute to the overall risks estimated at evaluated sites. Risk driver chemicals are identified as constituents of concern (COCs) for further evaluation beyond this RI Report. Based on the presence of chemical PCOCs at levels greater than applicable screening levels, the following area of the IAAAP was retained for further evaluation in the HHRA:

- Firing Sites Area (FS Area)

Descriptions of the above-listed area and a summary of historical operations are provided in Sections 1.4 and 1.5, respectively, of this RI Report.

6.1 PURPOSE AND APPROACH

The purpose of this HHRA is to provide USACE, the regulatory agencies, and other IAAAP stakeholders with a decision-making tool for use in determining the need for further investigation or site cleanup based upon present site conditions. The regulatory mandate from the National Contingency Plan (NCP) (USEPA, 1990) is to protect human health and the environment. The HHRA evaluates potential risks for the above-listed areas at IAAAP using a conservative methodology to ensure that this mandate is achieved. The specific objectives of this HHRA are as follows:

- Develop lists of COPCs for contaminants detected on site that were identified as PCOCs during previous investigation, and that have been carried forward from Section 4.0 of this RI Report into the HHRA. COPCs are then quantitatively evaluated in the HHRA to determine human health carcinogenic and noncarcinogenic risks.
- Identify current and future land use patterns, potentially exposed populations, and pathways/routes by which exposures may occur.
- Estimate exposure point concentrations based on the U.S. Environmental Protection Agency's (USEPA) reasonable maximum exposure (RME) scenarios.
- Estimate potential baseline human health risks associated with the IAAAP if no further action (NFA) occurs. Significant COPCs (i.e., those COPCs associated with cancer and/or non-cancer risks exceeding USEPA's de minimis target risk values) are labeled as COCs.

The general approach used for conducting the HHRA follows U.S. Environmental Protection Agency (USEPA) and U.S. Army Corps of Engineers (USACE) risk assessment guidance and data quality objectives (DQO) process. The chief risk assessment guidance documents that form the basis of the HHRA approach are listed below. Other guidance documents and scientific literature are cited as appropriate in the text.

- Risk Assessment Guidance for Superfund, Volume I, Human Health Evaluation Manual: Part A (USEPA, 1989)
- Risk Assessment Guidance for Superfund (RAGS), Volume I, Human Health Evaluation Manual: Part B, Development of Risk-Based PRGs (USEPA, 1991)

- Integrated Risk Information System (IRIS) (USEPA, 2007)
- Preliminary Remediation Goals (Industrial), USEPA Region 9 (USEPA, 2004b)

The DQO process consists of a series of planning steps, based on the scientific method, that are designed to ensure that the type, quantity, and quality of environmental data used in decision-making are appropriate for their intended purpose. The DQO process was followed in this risk assessment to identify potential risks to evaluated receptor populations.

The radiological risk assessment for potential human receptors at the IAAAP site is presented in Section 8.0 of this RI report. The risk estimates are not based on observed impacts to actual people, but rather, are developed using mathematical models as opposed to actual observed or measured effects. Therefore, these risk estimates should be used only within the CERCLA framework for which they are intended and not for any other purpose such as the development of health advisories.

The main components of the HHRA, and the organization of those components as presented in this section are described in the following items

- Section 6.2: Data Usability. Summarizes the overall process that will be applied in evaluating data usability and a discussion of data collected to date that will be incorporated into the risk calculations.
- Section 6.3: Exposure Assessment. Presents the land use and potentially exposed people, conceptual site model (CSM), methodology for estimating exposure point concentrations (EPCs), intake equations, and exposure factor values.
- Section 6.4: Identification of Constituents of Potential Concern. Discusses the methodology and result of COPC Selections for areas and media of concern.
- Section 6.5: Toxicity Assessment. Describes the approaches for evaluating chemical toxicity.
- Section 6.6: Risk Characterization. Describes the methodology used for the estimation of health hazard and cancer risk, and discusses sources and implications of uncertainty in the risk characterization.
- Section 6.7: Uncertainty Analysis. Discusses sources and implications of uncertainty in the risk assessment process, including site-specific factors contributing to the overall uncertainty of the of the risk characterization results.

6.2 DATA USABILITY

The first step in the HHRA process is to evaluate existing data and data generated during the RI to determine whether they are of adequate quality for use in quantifying risks. Data judged to be of adequate quality was further reviewed to determine whether detection limits were sufficiently low for the intended risk assessment. Data quality is generally assured through the implementation of standard operating procedures during sample collection and sample analysis, quality control checks, and data review and validation. The IAAAP HHRA database consists of analytical results for samples collected from May 2001 through October 2007. All chemical data collected during both the TN&A RI and the 2006 – 2007 FUSRAP RI were reviewed and validated to ensure that the data quality is sufficient for quantifying risk.

Qualifiers pertaining to uncertainty in the identity or the reported concentration of an analyte were assigned to certain analytical data by the laboratories or by chemists performing data validation. Presented in Table 6-1 are various qualifiers used in validating data, their definitions, and an explanation of how the qualified data was used in the HHRA.

Table 6-1. Qualifiers Used in Validating Data

Qualifier	Definition	Use of Qualified Data in the Baseline Risk Assessment
U	The analyte was not detected above the reported laboratory method detection limit.	If the analyte was selected as a COPC, then it was assumed to be present at one-half of the method detection limit for risk calculations.
J	The analyte was positively identified; however, the associated numerical value is an estimate of the concentration of the analyte.	If the analyte was selected as a COPC, it was assumed to be present at the estimated concentration.
UJ	The analyte was not detected above the reported method detection limit. The reported method detection limit is an estimated value and may not represent the actual limit above which the analyte can be accurately and precisely measured.	If the analyte was selected as a COPC, then it was assumed to be present at one-half of the method detection limit.
R	The sample results are rejected and are, therefore, unusable due to serious deficiencies in the ability to analyze the sample and meet quality control criteria. The presence or absence of the analyte cannot be verified.	R qualified data are not used in the risk assessment.

A review of previously collected data follows in Section 6.2.1. Section 6.2.2 describes the IAAAP areas of concern, PCOCs and the environmental data collected during the Phase II RI used to perform the HHRA.

6.2.1 Previously Collected Data

Over the past years, multiple investigations have been conducted at the IAAAP under the direction of multiple federal agencies. Sections 1.5 and 1.6 of this RI Report provide operational descriptions and investigative histories for each area of concern covered by this HHRA. Section 1.5 of the RI Work Plan identifies PCOCs and investigative objectives for each of the areas of concern. Additional information on the process used to compile and evaluate existing data is provided in Section 2.3.1 of the RI Work Plan.

The IAAAP RI completed in May 1996, included a HHRA to identify potential adverse impacts to human health. After excluding chemicals never detected, chemicals rarely detected, and

essential human nutrients, the 1996 IAAAP HHRA identified 88 COPCs (Table 2-6 of the 1996 IAAAP HHRA) (US Army Environmental Center, 1996). COPCs found to exhibit levels of risk above USEPA's risk criteria were identified as COCs in the 1996 IAAAP HHRA. Of the COPCs, explosives were identified as the major COC group, with metals and semi-volatile organic compounds (SVOCs) as additional COCs present in some areas.

The August 1998 Soils OU #1 Record of Decision (ROD) , although not directly applicable to the eight FUSRAP sites evaluated in this RI, contains Remedial Goal (RG) values (Table 13 and 14 of the ROD) for 17 chemicals, including metals, polycyclic aromatic hydrocarbons (PAHs), explosives, and polychlorinated biphenyls (PCBs). The August 1998 ROD states that these chemical-specific RGs were established at the $1x10^{-6}$ carcinogenic risk level for a reasonably maximum exposed (RME) individual exposed to soil through dermal contact and incidental ingestion under an industrial land use setting.

The list of RGs presented in the August 1998 ROD include those chemicals which were identified in the 1996 IAAAP HHRA as demonstrating risks for on-site workers (i.e., 2,4,6-trinitrotoluene (TNT), cyclotrimethylene trinitramine (RDX), trinitrobenzene, arsenic, beryllium, PCBs, and benzo(a)pyrene). However, in addition to those seven chemicals, ten more chemicals (i.e., antimony, cadmium, chromium VI, lead, thallium, benzo(a)anthracene, benzo(b)fluoranthene, dibenz(a,h)anthracene, dinitrotoluene, and cyclotetramethylene tetranitramine (HMX)) were presented with RGs in the August 1998 ROD, but without a discussion as to why they were added to the list. The ROD states that when appropriate toxicological information was available, RGs were calculated at $1x10^{-6}$ cancer risk level for an industrial worker exposed to soil through dermal contact and incidental ingestion but the 1996 IAAAP HHRA included quantitative evaluation for worker exposure only for the incidental ingestion pathway. The 1996 IAAAP HHRA discusses dermal contact with contaminants in soil and inhalation of contaminants in air, but these exposure routes were judged to be of little significance and were therefore, not evaluated quantitatively.

6.2.2 Area of Concern Descriptions, Preliminary Constituents of Potential Concern and Investigative Findings

During past investigations constituents that may have been used at an investigative area based on operational history have been identified as PCOCs. A review of existing data from previous investigations was used to evaluate the presence of the PCOCs at each investigative area. PCOCs needing further investigation were targeted for additional investigation during the Remedial Investigation (RI). A brief description of each area of concern, a list of PCOCs for each area based on previous investigations and its operational history, and the investigative outcomes for each area of concern are provided in Section 4 of this RI Report. Figure 1-3 shows the locations of each investigative area of concern. The list of PCOCs for each area was developed from an extensive review of existing operational and investigative reports. A summary of the operational and investigative history of each area of concern has been compiled and presented in the RI Work Plan (USACE, 2007).

6.3 EXPOSURE ASSESSMENT

The exposure assessment evaluates potential exposure for receptor populations reasonably anticipated to be exposed to soil COPCs (to be identified in Section 6.4). The exposure assessment is performed in three steps. First the exposure setting is characterized using available

site-specific information. A description of the IAAAP exposure setting, in terms of land use and potentially exposed populations is presented in Section 6.3.1.

Second, physical descriptions of each area are provided in Section 1.4 of this RI Report. This information was then used to graphically construct a Conceptual Site Model (CSM) in order to schematically depict potentially complete exposure pathways between chemical sources and potential receptors.

In the third step of the exposure assessment, dose or intake of COPCs for each receptor resulting from contact with contaminated media are calculated. First, exposure point concentrations (EPCs) are quantified for each COPC identified for each area and medium of concern as discussed in Section 6.3.4. The EPCs are calculated to evaluate reasonable maximum exposure (RME) scenarios, in accordance with USEPA guidance (USEPA, 2002). EPCs are also used in Section 6.4 to determine COPCs to be retained for quantitative risk evaluation in this HHRA. The general equations used to quantify exposure to contaminated media at the IAAAP, in terms of average daily intakes (ADIs), are presented in Section 6.3.5. ADIs, which are later used to calculate potential carcinogenic and noncarcinogenic risks, are quantified for all identified receptors using EPCs in conjunction with conservative (90-95th percentile) or RME scenario exposure assumptions.

6.3.1 Identification of Land Use and Potentially Exposed Populations

The HHRA will focus on those receptors that are likely to be maximally exposed to contaminated soil under current and future exposure scenarios. This approach ensures that maximum potential risk will be characterized and that all potential receptors will be adequately protected. Although the IAAAP serves a military mission, current land use is considered mainly industrial in nature due to on-going ordinance production activities. Because it is expected that these activities will continue into the future, future land use is expected to remain industrial. There are no plans for future residential development of any of the sites being evaluated in the HHRA.

Post operational activities at the IAAAP have resulted in releases of chemicals and radionuclides to environmental media that may pose risk to human receptors. However, the scope of the HHRA is to address chemical contamination in surface and subsurface soil only. Potential human exposures to radiological contamination in soil will be separately and quantitatively evaluated in Section 8.0 (Radiological Risk Assessment) of this RI Report. Because land use is industrial, and because the scope of this HHRA is limited to evaluation of potential soil exposures, potentially exposed populations at the site to be evaluated in this HHRA will include current and future site workers and future construction workers. Based on assumed occupational patterns, site (industrial-type) workers may become exposed to surface soil only, at the 0 to 1 ft depth interval (bgs). However, for construction workers, potential exposures to soil within the 0 to 10 ft depth interval are assumed during excavation activities.

Because of access restrictions to the IAAAP property, as well as the physical characteristics of each area therein, exposures to potential trespassers and recreational users (e.g., hunters) are considered infrequent and insignificant. Additionally, exposures to offsite individuals (e.g., via air transport, runoff, etc.) is considered insignificant due to the large distances of the evaluated areas from potential offsite receptor locations.

In summary, current and future scenarios to be evaluated in this HHRA include the following:

- current and future IAAAP workers, exposed to surface soils 0 to 1 feet below land surface, and
- future construction workers, exposed to soil 0 to 10 feet below land surface.

6.3.2 Conceptual Site Model

The CSM is a graphical representation of the exposure pathways identified for potential receptor populations at the IAAAP (Figure 6-1). The CSM summarizes the pathways that hazardous substances may take to reach potential receptors. The CSM provides the foundation upon which to develop the subsequent stages of the exposure assessment. It will also assist in indicating what types of information must be collected. The CSM shows complete exposure pathways that will be retained for further evaluation in the risk assessments.

A complete exposure pathway includes all of the following elements:

- a source and mechanism of contaminant release,
- a transport or contact medium (e.g., soil),
- an exposure point where humans could contact the contaminated medium, and
- an exposure (intake) route (such as ingestion or inhalation).

The absence of any one of the above elements results in an incomplete exposure pathway. Where there is no potential exposure, there is no potential risk. USEPA's risk assessment and risk characterization guidance does not require that all plausible exposure scenarios and exposure pathways be assessed. Pathways that are incomplete or potentially complete, but deemed to be negligible, do not require evaluation. Potentially complete but negligible pathways are identified on the CSM but will not be evaluated quantitatively because these pathways are unlikely to measurably affect risk estimates or cleanup decisions. For example, exposure to sediment may potentially occur at some of the exposure units. Since the receptors at these locations will be working and occupational exposure to sediments is expected to be limited if it occurs at all, this exposure pathway is considered to be negligible and will not be evaluated quantitatively.

6.3.3 Pathways to be Evaluated Quantitatively in the Risk Assessment

As indicated by the CSM, the following exposure pathways appear to be complete and will, therefore, be quantitatively evaluated:

- soil ingestion,
- dermal absorption from soil,
- inhalation of dust.

For this HHRA, the soil source terms or EPCs will be estimated using the lower of the 95% UCL (USEPA, 2002) or the maximum detected constituent concentration for the COPC in a defined exposure unit (see Section 6.3.4). Non-detect values will be evaluated based upon ½ the sample MDL as a proxy concentration.

Soil will be segregated into two populations, from which all summary statistics and EPCs will be calculated:

- surface soil – all samples collected from 0 to 1 foot depth, and
- subsurface soil – all samples collected from 0 to 10 feet bgs.

Since construction work rarely extends below 10 feet bgs this level will be used as a conservative cut off.

6.3.4 Methodology for Estimating Exposure Point Concentrations

To calculate cancer risk or non-cancer hazard, an estimate must be made of the chemical concentration in the environmental medium to which an individual may be exposed. Per USEPA guidance (USEPA, 2002a), this is accomplished by deriving an exposure point concentration (EPC). The EPC should be the estimate of the average concentration measured over the area to which an individual receptor would be exposed for the duration of the exposure. Because of the uncertainty associated with estimating the true average concentration at a site, USEPA recommends that the lesser of the 95% upper confidence level (UCL) or the maximum detected concentration be used as the appropriate estimate of the average site concentration for a reasonable maximum exposure (RME) scenario (USEPA, 2002a). Essentially, the 95% UCL is a conservative, upper-estimate of the mean concentration, and by using the 95% UCL, the probability of underestimating the true mean is less than 5%. The 95% UCL also accounts for uncertainties resulting from limited sampling (Gilbert, 1987). Under certain situations involving small sample sizes, the 95% UCL may be greater than the maximum concentration. For this reason, USEPA recommends the selection of the lesser of the two as the appropriate EPC.

The 95% UCL was calculated in accordance with Gilbert's *Statistical Methods for Environmental Pollution Monitoring* (Gilbert, 1987) and *Calculating Upper Confidence Limits for Exposure Point Concentrations at Hazardous Waste Sites* (USEPA, 2002a). Before calculating the 95% UCL, the distribution of the data set was determined. If the data were found to be normally distributed, the EPC was calculated as the 95% UCL of the arithmetic mean of the data, using the Student's t-statistic (USEPA, 2002a). If the data was found to be log normally distributed, the EPC was calculated as the 95% UCL using the H-statistic (USEPA, 2002a). The USEPA 2002 guidance also presents methodology to consider if the data distributions are neither normal nor lognormal and further, USEPA recommends the use of Pro-UCL software (USEPA, 2004a) for the evaluations of data distributions, as well as their appropriate 95% UCL values.

The following equation was used for data fitting a lognormal distribution:

$$UCL = e^{\left[\bar{x} + 0.5s^2 + sH/(n-1)^{1/2}\right]}$$

where:

UCL = upper confidence limit
e = constant (base of the natural log, equal to 2.718)
$\bar{x}$ = mean of the log-transformed data
s = standard deviation of the log-transformed data
H = H-statistic (Gilbert, 1987)
n = number of samples

The following equation was used for data fitting a normal distribution:

$$UCL = \bar{x} + t(s/\sqrt{n})$$

where:

UCL = upper confidence limit
$\bar{x}$ = mean of the untransformed data
s = standard deviation of the untransformed data
t = Student t-statistic based on an α level (significance level) of 0.05 and n-1 degrees of freedom
n = number of samples

For data that does not fit a normal or lognormal distribution, the 95% UCL using the Z-statistic is used. This method, based on the normal distribution as described by Gilbert (1987), provides an approximate one-sided UCL of the mean for a population assuming any distribution.

The following equation was used for data fitting neither the normal nor lognormal distribution:

$$UCL = \overline{x} + Z_{1-\alpha}(s/\sqrt{n})$$

where:

UCL = upper confidence limit
$\overline{x}$ = mean of the untransformed data
s = standard deviation of the untransformed data
$Z_{1-\alpha}$ = Z-parameter based on an α of 0.05
n = number of samples

Environmental chemical data populations typically contain data that are reported below a given MDL, referred to as "nondetect" (U or UJ qualified) data. The mean cannot be estimated unless numerical values are assigned to these nondetect data. For chemical analytical results, USEPA's *RAGS* (1989) recommends that one-half the sample MDL be used as a proxy value for "not detected" results. Therefore, for the purposes of calculating descriptive statistics for chemicals evaluated in this HHRA, nondetect data was substituted by a value of one-half of the reported MDL as a surrogate concentration.

For ease of calculation, Pro-UCL, version 4.0, software (USEPA, 2007) was utilized to calculate all statistical parameters, in addition to the 95% UCL, for each chemical data population. The summary of descriptive statistics for COPCs in site media are presented on Tables 6-2 and 6-3 for surface soil and surface plus subsurface soil, respectively. Summary statistics and information presented on these tables include the following for each chemical: data distribution; frequency of detection; mean, minimum, maximum, and 95% UCL concentrations; and the selected EPC. The 95% UCL will be used as the EPC except in cases where the maximum detected value is less than the EPC. In these cases, the maximum detected value will be used as the EPC, not the 95% UCL.

Based on the USEPA Region 9 PRG exceedances in Section 4, EPCs were calculated for chemicals detected at the FS-6, 7, 8, & 15 area. The data used for calculating EPCs in this area includes the 2006 – 2007 FUSRAP RI data, as well as data acquired by TN & Associates and presented in the Supplemental RI Report (TN&A, 2002). The results of both investigations were collected to verify and/or confirm the previously existing JAYCOR RI sample locations and results. Blind field duplicates were collected to assess variability in the sampling process. Duplicate samples were used in the data quality assessment but will not be included in the calculation of the EPCs. The maximum detected concentration was used as the EPC for data sets with less than eight observations ($n<8$) because, in such cases, a minimum of eight observations are not available to reliably determine a data set distribution (USEPA, 2002). For "J" data, which was greater than the MDL reported without the sample MDL, the value was used as reported. Samples reported as ND or zero with no MDL will not be utilized in calculating a 95%UCL. Data flagged with an "R", meaning rejected, will also not be used in calculating the EPC.

[a]Individual sample comparisons to EPA Region 9 PRGs were performed for subsurface soils (1 to 10 ft bgs) and no exceedances were noted. Exceedences were only noted in surface soil; therefore, surface soil statistics and EPCs were applied over the 0 to 10 ft bgs interval.

[a]%FOD - Frequency of detection expressed as percent.

[b]EPC - Exposure point concentration determined to be the lesser of the 95% UCL and the maximum detected concentration.

[c]PRG - EPA Region 9 preliminary remediation goal for industrial exposures (EPA, 2004).

[d]NE - Does not exceed an EPA Region 9 PRG by an individual sample concentration. See Appendix C.

[e]NA - Information is not applicable to range of nondetects columns because the parameter was detected in all samples analyzed.

6.3.5 Pathway-Specific Intake Equations

The following presents equations used to calculate ADIs for soil exposure routes. Table 6-4 presents exposure parameters that were used for evaluating human health risks for receptors at the IAAAP areas of concern. Tables 1 through 10 of Appendix C present ADI calculation spreadsheets for both receptors and all exposure routes being evaluated in this HHRA.

Average daily chemical intake for the incidental ingestion of soil will be calculated by use of the following formula (USEPA, 1989):

$$ADI_{Ing} = \frac{CS \times IR \times CF \times FI \times EF \times ED}{BW \times AT}$$

where:

ADI_{Ing} = average daily chemical intake via soil ingestion (mg/kg-day)
CS = constituent concentration in soil (mg/kg)
IR = ingestion rate (mg soil/day)
CF = conversion factor (10^{-6} kg/mg)
FI = fraction ingested from contaminated source (unitless)
EF = exposure frequency (days/year)
ED = exposure duration (years)
BW = body weight (kg)
AT = averaging time (period over which exposure is averaged, days)

Average daily chemical intake by inhalation of soil particles (and volatiles, if required) was calculated using of the following formula (USEPA, 1989):

$$ADI_{Inh} = \frac{CA \times IR \times ET \times EF \times ED}{BW \times AT}$$

where:

ADI_{Inh} = average daily chemical intake via inhalation (mg/kg-day)
CA = constituent concentration in air (mg/m^3)
IR = inhalation rate (m^3/hour)
ET = exposure time (hours/day)
EF = exposure frequency (days/year)
ED = exposure duration (years)
BW = body weight (kg)
AT = averaging time (period over which exposure is averaged, days)

The chemical concentration in air (CA) term was calculated as follows:

$$CA = CS \times [(1 / PEF) + (1 / VF)]$$

where:

CS = Concentration in soil (mg/kg)
PEF = Particle emission factor (m^3/kg) (See explanation that follows.)
VF = Volatilization factor (m^3/kg)

The PEF relates the concentration of the contaminant in soil to the concentration of respirable particles in the air from fugitive dust emissions resulting from wind erosion. To estimate dust inhalation exposure to site workers and construction workers, USEPA's (2002) default value of 1.36×10^9 m^3/kg was applied.

Table 6-4. Exposure Assumptions

Exposure Pathway/Parameter	Units	Future Construction Worker (Adult)	Current & Future Site Worker (Adult)	Reference

The chemical VFs were calculated as presented in the following formula (USEPA, 1996a):

$$VF = \frac{(Q/C) \times (3.14 \times D_A \times T)^{1/2} \times 10^{-4}\ (m^2/cm^2)}{(2 \times \rho_b \times D_A)}$$

where:

$$D_A = \frac{[(\theta a^{10/3}\ Di\ H' + \theta w^{10/3}\ Dw)/n^2]}{\rho_b Kd + \theta w + \theta a\ H'}$$

and where:

VF = volatilization factor, m^3/kg
Q/C = air dispersion factor, g/m^2-s per kg/m^3
D_A = apparent diffusivity, cm^2/s
T = exposure interval, time, sec
ρ_b = dry soil bulk density, g/cm^3
θa = air-filled soil porosity, n - θw
n = total soil porosity, $1 - (\rho_b/\rho_s)$
θw = water-filled soil porosity, 0.15
Di = diffusivity in air, cm^2/s, chemical specific
H' = dimensionless Henry's law constant, chemical specific
Dw = diffusivity in water, cm^2/s, chemical specific
Kd = soil-water partition coefficient, cm^3/g, K_{OC} x f_{OC} (organics), chemical specific
K_{OC} = soil organic carbon partition coefficient, cm2/g, chemical specific
FOC = fraction organic carbon in soil, g/g, 0.006

Average daily chemical intake for dermal absorption of chemicals in soil was calculated using the following formula (USEPA, 2004):

$$ADI_{Derm} = \frac{CS \times CF \times SA \times AF \times ABS \times SCT \times EF \times ED}{BW \times AT}$$

where:

ADI_{Derm} = average daily absorbed chemical dose (mg/kg-day)
CS = constituent concentration in soil (mg/kg)
CF = conversion factor (10^{-6} kg/mg)
SA = skin surface area available for contact (cm^2)
AF = soil to skin adherence factor (mg/cm^2)
ABS = absorption factor (unitless)
SCT = soil contact time; fraction of day soil remains on skin (unitless)
EF = exposure frequency (days/year)
ED = exposure duration (years)
BW = body weight (kg)
AT = averaging time (period over which exposure is averaged, days)

6.3.6 Exposure Factor Values

Industrial land use currently occurs within the IAAAP areas of concern, so adult industrial workers were identified as potential receptors. These receptors could be exposed to residual contamination present in surface soil (0-1 feet below land surface) but are not expected to have regular contact with subsurface soil. Site workers are assumed to be on the job 8 hours per day, 250 days per year over a 25-year period. Since site workers are assumed to be adults, a body weight of 70-kilogram was used to assess exposure to COPCs.

Exposure pathways evaluated for the industrial site worker scenario include:

- incidental ingestion of surface soil (0-1 feet below land surface);
- inhalation of airborne contaminated dust or volatile emissions from surface soil (0-1 feet below land surface); and
- dermal exposure to surface soil (0-1 feet below land surface).

Site workers are not expected to have regular contact with subsurface soil or sediments. The parameters used to evaluate site worker exposures and their references are provided in Table 6-4.

Since it is reasonable to assume that construction activities could occur within the IAAAP areas of concern, adult construction workers were also identified as potential receptors. During construction activities these receptors could be exposed to residual contamination present in soil 0-10 feet below land surface. Construction workers were assumed to be on the job 8 hours per day, 250 days per year over a 1-year period. Since construction workers are assumed to be adults, a body weight of 70-kilogram will be used to assess exposure to COPCs.

Exposure pathways evaluated for the construction worker scenario include:

- incidental ingestion of soil 0-10 feet below land surface;
- inhalation of airborne contaminated dust or volatile emissions from soil 0-10 feet below land surface; and
- dermal exposure to soil 0-10 feet below land surface.

Construction workers are not expected to have regular contact with sediment. The parameters used to evaluate these pathways and their references are provided in Table 6-4.

6.4 IDENTIFICATION OF CONSTITUENTS OF POTENTIAL CONCERN

As discussed in the RI Work Plan (USACE, 2007), soil PCOCs were determined through review of historical operations as well as data generated during previous investigations. This HHRA includes data collected during those previous investigations, in conjunction with data acquired during the recent 2006-2007 FUSRAP RI. Because of the availability of newly acquired data, all sample results (including those from previous investigations) were compared against EPA Region 9 Industrial PRGs for the purpose of determining the nature and extent of the presence of each detected constituent in soil. Region 9 Industrial PRG comparisons were conducted for surface soil (0 to 1 ft bgs) data and then for subsurface soil data (greater than 1 ft bgs). The Region 9 Industrial PRG used as the screening concentration was selected as the lower of the industrial soil PRG and the soil screening level (SSL) protective of leaching to groundwater.

If at least one sample concentration of a chemical exceeded the selected screening concentration, then that chemical was retained for an additional screening evaluation to determine if the chemical should be retained as a COPC for quantitative risk analysis in this HHRA. The following summarizes the general, stepwise approach used for identifying COPCs:

- Analytes with no single point that exceeded the PRG (or surrogate PRG) in Section 4.0 of this report were not carried forward for further evaluation for that area;
- Analytes with no established PRG and no detectable concentrations were not carried forward for further evaluation for that area;

- Analytes without an established PRG that exhibited detectable concentrations were carried forward for qualitative evaluation. Essential nutrients (calcium, magnesium, potassium, sodium, etc.) were not further evaluated, qualitatively or quantitatively for that area.
- An area Exposure Point Concentration (EPC) was then calculated for each remaining analyte by area. If the EPC for the area did not exceed the applicable PRG, the analyte was eliminated from further evaluation in the HHRA.
- All remaining analytes were retained as COPCs in the respective areas for site specific risk analysis.

The COPC selection process for the HHRA is discussed in greater detail in Section 6.4.2. Prior to discussion of the COPC selection process, the following section (6.4.1) describes the basis of the Region 9 PRGs for use as risk-based screening concentrations in this RI Report and HHRA."

6.4.1 U.S. EPA Region 9 Industrial Preliminary Remediation Goals

Risk-based screening levels are compound-specific concentration limits that are compared to site data to determine if a constituent in an investigative area poses a potential risk to site workers. Compounds which exceed their respective risk-based screening level are retained for further analysis in the HHRA.

For the HHRA, soil data were evaluated on an area-by-area basis. Data were sorted by area of concern, environmental media and analytical group. Results for each analyte were compared to risk-based screening levels selected as the lower of the USEPA Region 9 soil PRGs for direct contact under an industrial setting, and the Soil Screening Level (SSL) for the protection of groundwater (USEPA, 2004). The USEPA Region 9 Industrial PRGs are chemical-specific concentrations that correspond to fixed levels of risk (i.e. either a one-in-a-million [$1x10^{-6}$] excess cancer risk or a noncancer HQ of 1 in soil, air, or water). If a substance causes both cancer and noncancer (systemic) effects, the more stringent criteria is selected as the PRG. The PRGs are calculated using the same exposure equations and parameters used to calculate carcinogenic and non-carcinogenic risk, however, instead of solving for risk, the equations are used to solve for a chemical concentration that corresponds to a specified target acceptable risk levels. Complete exposure pathways included for industrial use PRGs calculations include ingestion, inhalation of particulates, inhalation of volatiles, and dermal absorption from soil.

Most Region 9 Industrial PRGs are derived using standard equations; however, some PRGs are derived with special considerations. For instance, the PRG for cadmium is based on the oral reference dose (RfD) for water which is slightly more conservative (by a factor of 2) than the RfD for food. The RfD for food could be more applicable for soil exposures but the PRG based on water consumption was selected to be conservative. The PRG for total chromium, which was applied to both data screening in Section 4 of the RI report and is used for COPC identification in the HHRA, assumes a 1:6 ratio of hexavalent chromium to trivalent chromium. At the IAAAP, chromium was analyzed and detected in soil samples collected from IAAAP areas as total chromium. Uncertainty exists regarding the actual valence form of chromium detected in site soils. However, according to ATSDR (1994), chromium compounds, mostly in the chromium(III) or chromium(VI) forms, are produced and used by the chemical industry for chrome plating, the manufacture of dyes and pigments, leather tanning, and wood preserving. Smaller amounts are used in drilling muds, rust and corrosion inhibitors, textiles, and toner for copying machines. Because these potential sources are not consistent with historical site activities at the IAAAP, the total chromium PRG was used in the Section 4 data screening and in the HHRA evaluation of chromium as a COPC.

When Region 9 first published the PRG table there were some discrepancies between California EPA (Cal-EPA) and U.S. EPA regarding toxicities values, with the Cal-EPA values being the significantly more protective than the risk-based PRGs calculated using U.S. EPA toxicity values. Since the Cal-Modified PRGs are more stringent than the federal numbers, Cal-Modified PRGs were used when available.

6.4.1.1 USEPA Region 9 Ceiling Limit for Iron

For some SVOCs and inorganics of known low toxicity, USEPA Region 9 assigns a PRG value equivalent to a default, non-risk-based "ceiling limit" of 100,000 mg/kg. This ceiling limit is controversial among regulators, even among those with Region 9. However, Region 9 also presents risk-based values for some low-toxicity SVOCs and inorganics in their "Intercalc Table" if toxicity criteria are available for calculating those values.

Following performance of data comparisons using the ceiling limit PRGs, iron was the only chemical detected at concentrations in the investigated areas that exceeded 100,000 mg/kg. Subsequently, the corresponding risk-based value in Region 9's Intercalc table was reviewed and determined to be more appropriate for use in the data comparisons for iron. Therefore, the ceiling limit PRG for iron was replaced with the risk-based value in the data comparisons.

The following is an excerpt from the Region 9 Technical User's Guide explaining the use of the 100,000 mg/kg ceiling limit as a PRG for some chemicals:

"With respect to applying a "ceiling limit" for chemicals other than volatiles, it is recognized that this is not a universally accepted approach. Some within the agency argue that all values should be risk-based to allow for scaling (for example, if the risk-based PRG is set at a hazard quotient = 1.0, and the user would like to set the hazard quotient to 0.1 to take into account multiple chemicals, then this is as simple as multiplying the risk-based PRG by 1/10th). If scaling is necessary, PRG users can do this simply by referring to the "InterCalc Tables" at our website where risk-based soil concentrations are presented for all chemicals (see soil calculations, "combined" pathways column).

In spite of the fact that applying a ceiling limit is not a universally accepted approach, we have opted to continue applying a "max" soil concentration to the PRG Table for the following reasons:

1) Risk-based PRGs for some chemicals in soil exceed unity (>1,000,000 mg/kg), which is not possible.
2) The ceiling limit of 100,000 mg/kg is equivalent to a chemical representing 10% by weight of the soil sample. At this contaminant concentration (and higher), the assumptions for soil contact may be violated (for example, soil adherence and windborne dispersion assumptions) due to the presence of the foreign substance itself.
3) PRGs currently do not address short-term exposures (e.g. pica children and construction workers). Although extremely high soil PRGs are likely to represent relatively non-toxic chemicals, such high values may not be justified if in fact more toxicological data were available for evaluating short-term and/or acute exposures."

None of the above USEPA Region 9 concerns pertain to the use of the risk-based Intercalc value for iron, as addressed in the following items:

1) The exceedance of unity (i.e., >1,000,000 mg/kg), is not a concern for the Intercalc risk-based value for iron, which is 310,000 mg/kg.

2) Soil (dermal) contact assumptions are not violated by application of the risk-based value for iron, because the exposure route basis for this value is only ingestion.
3) The exposure assumptions used for the industrial-based value of 310,000 mg/kg reflect those used in the FUSRAP RI BRA and would be protective of both the industrial (site) worker and construction worker.

6.4.2 COPC Selection for the HHRA

In order to determine COPCs for this HHRA, surface soil (0 to 1 ft) and soil (0 to 10 ft) EPCs were calculated, for each area of concern (per Section 6.3.4 above), for those chemicals detected in at least one sample that exceeded the Region 9 Industrial PRG. Exceedances occurred only in surface soil data sets. Because no individual sample exceedances of screening levels occurred in subsurface soil (greater than 1 ft depth) data comparisons, EPCs calculated for surface soil were conservatively applied to evaluation of the 0 to 10 ft soil depth interval. EPCs were applied to COPC selection as concentrations representative of exposure conditions to receptors being evaluated in this HHRA. Surface soil EPCs, used to evaluate current and future site workers in each area, were calculated using sample data from the 0 to 1 ft depth interval. Soil EPCs, used to evaluate future construction workers in each area, who would be exposed to soils within the 0 to 10 ft depth were also calculated using soil sample data from the 0 to 1 ft depth interval for the reason previously stated earlier in this section. Therefore EPCs estimated for the construction worker using surface soil data result in a more conservative evaluation of this receptor, because the EPCs are likely higher than would have been estimated if all data from the 0 to 10 ft depth were applied. Those chemicals with EPCs exceeding corresponding Region 9 Industrial PRGs were retained as COPCs for further quantitative evaluation in this HHRA.

For many chemicals, there were few or no detects. If the frequency of detection for a chemical in either surface or subsurface soils was 5% or less (i.e., a minimum of one detection out of 20 analytical results), then generally, the chemical was excluded from the EPC comparisons with Region 9 Industrial PRGs. This rationale is consistent with USEPA's *RAGS* guidance (USEPA, 1989). Chemicals that exceeded the most stringent USEPA Region 9 Industrial PRG value were retained as COPCs for quantitative evaluation in the HHRA.

The final lists of COPCs retained in surface soil (0 – 1 ft bgs) and all soils (0 – 10 ft bgs) for further evaluation in this HHRA are presented Table 6-5.

Table 6-5. Summary of Soil Chemical Constituents of Potential Concern

COPCs	FS 1& 2	FS 3, 4 & 5	FS 6, 7, 8 & 15	FS 12	FS 14	Yard G	Yard C
Surface Soil (0 – 1 ft bgs)							
RDX	NE	NE	√	NE	NE	NE	NE
2,4,6-Trinitrotoluene	NE	NE	√	NE	NE	NE	NE
Aluminum	NE	NE	√	NE	NE	NE	NE
Chromium	NE	NE	√	NE	NE	NE	NE
COPCs	**FS 1& 2**	**FS 3, 4 & 5**	**FS 6, 7, 8 & 15**	**FS 12**	**FS 14**	**Yard G**	**Yard C**
Soil (0 – 10 ft bgs)							
RDX	NE	NE	√	NE	NE	NE	NE
2,4,6-Trinitrotoluene	NE	NE	√	NE	NE	NE	NE
Aluminum	NE	NE	√	NE	NE	NE	NE
Chromium	NE	NE	√	NE	NE	NE	NE

√ - Chemical retained as a COPC.
NE – Chemical was not retained as a COPC because of no exceedences of Region 9 Industrial PRG screening values.

6.5 TOXICITY ASSESSMENT

The toxicity assessment identifies toxicity values (i.e., slope factors and reference doses) for COPCs identified at the FUSRAP RI areas. These toxicity values were applied to the estimated doses (intakes) in order to quantify carcinogenic and noncarcinogenic risk. The toxic effects of a chemical generally depend not only upon the inherent toxicity of the chemical and the level of exposure (intake), but also on the route of exposure (oral, inhalation, or dermal) and the duration of exposure. Thus, a full description of toxic effects of a chemical includes a listing of what adverse health effects the chemical may cause, and how the occurrence of these effects depend upon intake, route, and duration of exposure.

The Integrated Risk Information System (IRIS) (USEPA, on-line) was used as the preferred source of toxicity values. If a toxicity value was not available through IRIS, then USEPA Industrial Region 9 PRG toxicity tables (on-line) were consulted. In some cases, toxicity criteria for similar constituents are used as surrogates for compounds that lack toxicity criteria. In other cases, there is no appropriate surrogate and so no risk calculation can be completed for those constituents. Based on COPCs identified for the HHRA, no surrogate compounds were incorporated to assess risk associated with compounds with no toxicity criteria. The lack of toxicological reference values for some constituents introduces uncertainty into risk-based screening and remedial action design. The potential impact of this uncertainty is discussed in Section 6.7 (Uncertainty Analysis) of this HHRA.

6.5.1 Cancer Toxicity Assessment

The USEPA slope factors (SFs) used for estimating cancer risks for non-radiological compounds are upper 95th percentile confidence limits of the probability of response per unit intake of chemical (by oral or inhalation routes) over a lifetime. SFs are based on mathematical extrapolation from experimental animal data and epidemiological studies, when available. SFs are expressed in units of risk per milligram chemical intake per kilogram body weight per day or $(mg/kg\text{-}day)^{-1}$. Because SFs are upper bound estimates, actual cancer potency of COPCs are likely lower than estimated (USEPA, 1989).

Cancer SFs used in this HHRA are presented in Tables 6-6, 6-7, and 6-8, for the oral, inhalation, and dermal pathways, respectively. The following information is presented for each COPC, as appropriate: weight of evidence classification, tumor site(s), unit risk values, uncertainty factors, and modifying factors.

Presently, toxicological data do not exist from which dermal SFs can be derived. To evaluate the dermal pathway, USEPA has adopted methodology to obtain dermal SFs by adjusting the oral SFs (USEPA, 2004). The equation for extrapolation of a default dermal SF is as follows:

$$\text{Default Dermal SF} = \frac{\text{Oral SF}}{\text{GI Absorption Factor (\%)}}$$

GI (Gastrointestinal) absorption factors used in this HHRA are obtained from USEPA's *RAGS: Part E, Supplemental Guidance for Dermal Risk Assessment* (USEPA, 2004). GI absorption factors not available in *RAGS Part E* were obtained online from the Risk Assessment Information System (ORNL, 2007).

For the inhalation pathway, cancer toxicity values are expressed in terms of the inhalation SF, having the units of $(mg\ chemical/kg\ body\ weight\ per\ day)^{-1}$. For purposes of risk assessment

ND = no data

development, inhalation SF values are converted into units of dose by utilizing the Unit Risk approach: the adult average body weight (70 kg), the upper-bound estimate for combined indoor-outdoor activity inhalation rate (20 m^3/day), and correcting for proper units, as in the following equation:

$$\text{Inhalation SF} = \frac{\text{Unit Risk } (\mu g/m^3)^{-1} \times 1000\ \mu g/mg \times 70\ kg}{20\ m^3/day}$$

Cancer SFs and associated supporting information, such as weight-of-evidence, target organ, oral absorption factors, etc., are presented in Tables 6-6, 6-7, and 6-8, for the oral, inhalation, and dermal pathways, respectively. The primary reference source for obtaining pertinent SFs for this HHRA was IRIS (USEPA, 2007).

6.5.2 Non-Cancer Toxicity Assessment

For noncancer health effects, the toxicity values are Reference Doses (RfDs). These are route- and duration-specific estimates of the average daily intake (mg chemical/kg-day) that may occur without appreciable risk of any adverse effect. Because the quality and quantity of toxicological data available to support derivation of RfD values vary among chemicals, USEPA also provides an indication of the overall confidence associated with each RfD value. In general, the lower the confidence, the more conservative USEPA is in deriving the RfD.

Oral RfDs are derived from toxicological data and can be easily obtained from USEPA toxicological databases. However, for the inhalation pathway, noncancer reference values are expressed in terms of the reference concentration (RfC), having the units of mg chemical/m^3 of air. For purposes of risk assessment development, inhalation RfC values can be converted into units of dose by multiplying by the inhalation rate (20 m^3/day) and dividing by the average adult body weight (70 kg), as in the following equation:

$$\text{Inhalation RfD} = \frac{\text{RfC} \times 20 m^3/day}{70\ kg}$$

Oral RfDs were adjusted to derive dermal RfDs in an approach similar as that described above for the derivation of dermal SFs, as follows:

Dermal RfD = Oral RfD x GI Absorption Factor (%)GI absorption factors used in this HHRA are obtained from USEPA's *RAGS: Part E, Supplemental Guidance for Dermal Risk Assessment* (USEPA, 2004). GI absorption factors not available in *RAGS Part E* were obtained online from the Risk Assessment Information System (ORNL, 2007).

Noncancer RfDs, and associated supporting information, are presented in Tables 6-9, 6-10, and 6-11, for oral, inhalation, and dermal pathways, respectively. Chronic RfDs were used for all populations in this risk characterization. The primary reference source for obtaining pertinent RfDs for this HHRA is the IRIS on-line database (USEPA, 2007), an USEPA reference source accessible on the internet at www.epa.gov/iris.

6.6 RISK CHARACTERIZATION

The objective of risk characterization is to integrate the information developed in the exposure assessment and the toxicity assessment into an evaluation of the potential current and future health risks associated with site COPCs. Because COPCs were only identified for Firing Site 6, carcinogenic and noncarcinogenic risks were only calculated for receptors at Firing Site 6. In this step, the toxicity factors (RfDs and SFs) will be applied in conjunction with intakes

Table 6-9. Toxicity Values: Noncarcinogenic - Oral (Ingestion)

ND = no data

calculated for each soil stratum, receptor, exposure route and COPC in order to estimate potential non-carcinogenic and carcinogenic health risk. The following describes how the risk calculations will be performed. All risk calculations performed for each receptor, exposure route, and COPC are presented in Appendix C, Tables 11 and 12. All total pathway carcinogenic and noncarcinogenic risks for each COPCs, by receptor, are presented in Table 6-12.

6.6.1 Carcinogenic Risk Characterization

The potential for carcinogenic effects are characterized in terms of the incremental probability of an individual developing cancer over a lifetime as a result of site-related exposure to a potential carcinogen, for chronic exposures. Excess lifetime cancer risk is estimated from the projected lifetime daily average intake and the cancer SF, which represents an upper bound estimate off the dose-response relationship. Excess lifetime cancer risk for chemical carcinogens is calculated by multiplying the estimated lifetime-averaged daily intake that is calculated for a chemical through an exposure route by the exposure route-specific (oral, inhalation, or dermal) cancer slope factor, as described below.

$$CR = DI \times SF$$

where:

CR = Cancer risk (unitless)
DI = Daily intake of chemical (mg/kg-day)
SF = Cancer slope factor $(mg/kg\text{-}day)^{-1}$

The risks resulting from exposure to multiple carcinogens are assumed to be additive. The total cancer risk will be estimated by summing the risks estimated for each COPC and for each pathway. This approach is likely to overestimate the incremental cancer risk, especially if several carcinogens are present, because the 95^{th} percentile estimates are not strictly additive (USEPA, 1989).

In the National Contingency Plan (USEPA, 1990), USEPA states that for known or suspected carcinogens, acceptable exposure levels are generally concentration levels that represent an excess upper-bound lifetime cancer risk of between 1.0E-06 and 1.0E-04. All carcinogenic risk levels for individual COPCs, as well as cumulative risks, were compared to USEPA's de minimis value of 1.0E-06. Individual COPCs with risks exceeding 1.0E-06, are identified as constituents of concern (COCs).

Tables presenting the calculation of cancer risks for all COPCs and exposure pathways at the Firing Site 6, 7, 8, and 15 Area are presented in Appendix C, Table 11 for site workers and Table 12 for construction workers. All risk results summed over all chemicals and pathways for both receptors are presented in Table 6-12. Those chemicals resulting in cumulative carcinogenic risks found to be greater than 1.0E-06 are designated in **BOLD** font. Carcinogenic risk results for receptors evaluated at the Firing Site 6, 7, 8, and 15 Area are discussed in Sections 6.6.1.1 and 6.6.1.2.

Table 6-12. Human Health Baseline Risk Assessment Summary
Current and Future Receptors
Cumulative Risks Summed for all Pathways
Firing Sites 6, 7, 8 & 15 Iowa Army Ammunition Plant, Middletown, Iowa

	Current and Future Site Worker[(1)]				Future Construction Worker[(1)]			
Chemical	**Carcinogenic Risks**	**% of Total CR**	**Noncancer HIs**	**% of HI**	**Carcinogenic Risks**	**% of Total CR**	**Noncancer HIs**	**% of HI**
RDX	**4.0E-06**	21.7%	0.034	0.82%	6.7E-07	24.3%	0.14	0.9%

(1)Current and future site workers were evaluated for exposures to COPCs in surface soil. Future construction workers were evaluated for exposures to COPCs in surface and subsurface soils (i.e., soils from the 0 to 10 ft b depth interval).

NA = not applicable; either no toxicity value exists or pathway not pertinent to this receptor.
Bold indicates carcinogenic risk exceeding 1E-06 and noncarcinogenic risk (HQ or HI) exceeding 1.0.

[NOTE: Chemical totals for noncarcinogenic risk (HI) are presented for illustative purposes only. It may not be appropriate to consider HIs for HQs summed over COPCs that represent adverse health effects for differng target organ effects.]

6.6.1.1 Current and Future Site Workers

Current and future site workers may be exposed to site soils, but only at the surface. Excess carcinogenic risks estimated for future site workers at the Firing Site 6, 7, 8, and 15 Area are shown in Table 6-13.

Table 6-13. Carcinogenic Risks Estimated for Future Site Workers

Exposure Media	Exposure Pathway	Carcinogenic Risk
Surface Soil	Incidental Ingestion	**5.9E-06**
	Dermal Contact	**1.0E-05**
	Inhalation	**2.6E-06**
	Total Risk	**1.8E-05**

All total pathway cancer risks exceed the de minimis criterion (1.0E-06), but are within USEPA's target cancer risk range of 1.0E-06 to 1.0E-04. Table 6-13 shows that the dermal pathway contributes predominantly to the total risk of 1.8E-05. Appendix C, Table 11 shows that dermal contact with 2,4,6-trinitrotoluene is the predominant COPC/exposure route combination contributing to the total risk. Table 6-12 shows that cumulative risks estimated for RDX, 2,4,6-trinitrotoluene, and chromium exceed 1.0E-06 and contribute approximately 22%, 66%, and 12% of the total cumulative risks summed across all pathways, respectively. Additionally, in order to determine if chromium concentrations are comparable to background, an EPC was calculated for chromium in background surface soil. By comparing site chromium with background chromium EPCs, it was determined that the EPC used to calculate FS-6, 7, 8, and 15 Area risks for site worker exposures to chromium in surface soil (3,106 mg/kg), exceeds the corresponding background concentration (16.6 mg/kg). Therefore, based on this analysis, RDX, 2,4,6-trinitrotoluene and chromium are identified as potentially carcinogenic COCs for site worker exposures to surface soil.

6.6.1.2 Current and Future Construction Workers

Current and future construction workers may be exposed to soils from the surface to an estimated depth of 10 ft (the typical excavation depth for building construction). Excess carcinogenic risks estimated for constructions workers at Firing Site 6 are shown in Table 6-14.

Table 6-14. Carcinogenic Risks Estimated for Construction Workers

Exposure Media	Exposure Pathway	Carcinogenic Risk
Surface and Subsurface Soil	Incidental Ingestion	**2.2E-06**
	Dermal Contact	4.0E-07
	Inhalation	1.0E-07
	Total Risk	**2.8E-06**

The total cancer risk for this receptor (2.8E-06) exceeds USEPA's de minimis criterion (1.0E-06), but is within USEPA's target cancer risk range of 1.0E-06 to 1.0E-04. Of the pathways evaluated, only the cancer risk estimated for the ingestion pathway exceeds 1.0E-06. Appendix C, Table 12 shows that ingestion of 2,4,6-trinitrotoluene in soil is the predominant COPC/exposure route combination contributing to the total risk. Table 6-12 shows that only the cumulative pathway risk for 2,4,6-trinitrotoluene exceeds 1.0E-06, contributing approximately 72% of the total cumulative risk summed across all pathways. Therefore, based on this analysis, 2,4,6 trinitrotoluene is identified as the only potentially carcinogenic COC for construction worker exposures to soil.

6.6.2 Noncarcinogenic Risk Characterization

The potential for noncarcinogenic health effects will be evaluated by the calculation of hazard quotients (HQs) which will be summed to yield hazard indices (HIs). An HQ is the ratio of the exposure duration-averaged estimated daily intake through a given exposure route to the chemical and route-specific (oral, inhalation, or dermal) reference dose, calculated as presented below.

$$HQ = DI / RfD$$

where:

HQ = Hazard quotient (unitless)
DI = Daily chemical intake (mg/kg-day)
RfD = Noncancer reference dose (mg/kg-day)

Use of the RfD assumes that there is a level of intake (the RfD) below which it is unlikely that even sensitive individuals, such as children, will experience adverse health effects over the period of exposure. If the average daily intake exceeds the RfD (that is, if the HQ exceeds 1), there may be cause for concern for potential non-cancer effects (USEPA, 1989). It should be noted, however, that the level of concern does not increase linearly as the RfD is approached or exceeded. Since the HQ does not define a dose-response relationship, its numerical value cannot be construed as a direct estimate of risk (USEPA, 1989). Rather, a HQ above 1 indicates a potential cause for concern for non-cancer health effects, which might indicate the need for reevaluating actual exposure conditions or concentrations or consideration of risk management alternatives.

To assess pathway-specific exposures to multiple chemicals, the HQ for each COPC is summed to yield a hazard index (HI). The assumption of additive effects reflected in the HI is most properly applied to substances that induce the same effect by the same biological mechanism (USEPA, 1989). Consequently, summing HQs for substances that are not expected to induce the same type of toxic effect will overestimate the potential for adverse health effects. The HI provides a measure of the potential for adverse effects, but it is conservative and dependent on the quality of experimental evidence.

If a receptor may be exposed by multiple pathways, the HIs from all relevant pathways are summed to obtain the total HI for that receptor. If the total HI is less than or equal to one, multiple-pathway exposures to COPCs at the site will be judged unlikely to result in an adverse effect. If the sum is greater than one, further evaluation of exposure assumptions and toxicity, including consideration of specific target organs affected and mechanisms of toxic actions of COPCs will be warranted to ascertain if the cumulative exposure would in fact be likely to harm exposed individuals.

Tables presenting the calculation of noncancer risks for all chemicals and exposure pathways are presented in Appendix C, Table 11 for site workers and Table 12 for construction workers. All HIs summed over chemicals and pathways for both receptors are presented in Table 6-12. Those chemicals resulting in noncarcinogenic risks greater than 1.0 are designated in **BOLD** font. Noncancer risk results for receptors evaluated at the Firing Site 6, 7, 8, and 15 Area are discussed in Sections 6.6.2.1 and 6.6.2.2.

6.6.2.1 Current and Future Site Workers

Current and future site workers may be exposed to site surface soils. HIs estimated for future site workers at the Firing Site 6, 7, 8, and 15 Area are shown in Table 6-15.

Table 6-15. HIs Estimated for Future Site Workers

Exposure Media	Exposure Pathway	HI
Surface Soil	Incidental Ingestion	**1.4**
	Dermal Contact	**2.4**
	Inhalation	0.36
	Total HI	**4.1**

The total HI estimated (4.1) for this receptor exceeds USEPA's target HI of 1.0. The total HI is driven by HIs estimated for the ingestion (1.4) and dermal contact (2.4) pathways, with the dermal pathway being the predominant pathway. Appendix C, Table 11 shows that dermal contact with 2,4,6-trinitrotoluene is the predominant COPC/exposure route contributing to the total HI. Table 6-16 shows that 2,4,6-trinitrotoluene contributes 60% of the total cumulative HI summed across all pathways. Though none of the individual pathway HIs for chromium presented in Appendix C, Table 11 exceed 1.0, Table 6-16 shows that the chromium HI for all summed pathways (1.4) exceeds 1.0. Additionally, in order to determine if chromium concentrations are comparable to background, an EPC was calculated for chromium in background surface soil. By comparing site chromium with background chromium EPCs, it was determined that the EPC used to calculate FS-6, 7, 8, and 15 Area risks for site worker exposures to chromium in surface soil (3,106 mg/kg), exceeds the corresponding background concentration (16.6 mg/kg). Therefore, based on this analysis, 2,4,6-trinitrotoluene, and chromium are identified as noncarcinogenic COCs for site worker exposures to surface soil.

Table 6-16. HIs Estimated for Construction Workers

Exposure Media	Exposure Pathway	HI
Surface and Subsurface Soil	Incidental Ingestion	**13**
	Dermal Contact	**2.4**
	Inhalation	0.36
	Total HI	**16**

None of the COPCs evaluated for this receptor affect similar target organs or cause similar critical effects; therefore, the noncarcinogenic risks are technically not additive. Consequently, the summing of HQs and HIs over all COPCs overestimates noncarcinogenic risks for this receptor. However, as discussed in Section 6.7.5.2, the primary outcome of the risk characterization, i.e., the identification of COCs, is not changed by not summing of noncarcinogenic risks over all COPCs.

6.6.2.2 Current and Future Construction Workers

Current and future construction workers are exposed to soils from the surface to an estimated depth of 10 ft (the typical excavation depth for building construction). HIs estimated for construction workers at Firing Site 6 are shown in Table 6-16.

The total HI estimated (16) for this receptor exceeds USEPA's target HI of 1.0. The total HI is driven by HIs estimated for the ingestion (13) and dermal contact (2.4) pathways, with the dermal pathway being the predominant pathway. Appendix C, Table 12 shows that ingestion and dermal exposures to 2,4,6-trinitrotoluene, as well as ingestion exposures to chromium, are the predominant COPC/exposure routes contributing to the total HI. Table 6-12 shows that 2,4,6-trinitrotoluene and chromium contribute approximately 59% and 36% of the total cumulative HI summed across all pathways, respectively. Additionally, in order to determine if chromium concentrations are comparable to background, an EPC was calculated for chromium

in background soil (0 to 10 ft). By comparing site chromium with background chromium EPCs, it was determined that the EPC used to calculate FS-6, 7, 8, and 15 Area risks for construction worker exposures to chromium in soil (3,106 mg/kg), exceeds the corresponding background concentration (20.7 mg/kg). Therefore, based on this analysis, 2,4,6-trinitrotoluene and chromium are identified as noncarcinogenic COCs for construction worker exposures to soil.

None of the COPCs evaluated for this receptor affect similar target organs or cause similar critical effects; therefore, the noncarcinogenic risks are technically not additive. Consequently, the summing of HQs and HIs over all COPCs overestimates noncarcinogenic risks for this receptor. However, as discussed in Section 6.7.5.2, the primary outcome of the risk characterization, i.e., the identification of COCs, is not changed by not summing of noncarcinogenic risks over all COPCs.

6.6.3 Summary of Risk Characterization

Soil at the FS-6, 7, 8, and 15 Area of the IAAAP was evaluated for potential carcinogenic and noncarcinogenic risks to current and future site workers and construction workers. None of the other sites investigated during the 2006-2007 FUSRAP RI, as well as during the previous investigations which are characterized in this RI Report, were quantitatively evaluated for human health risks in this HHRA because no COPCs were identified. At the FS-6, 7, 8, and 15 Area, current and future site workers were evaluated for exposures to RDX, 2,4,6-trinitrotoluene, aluminum, and chromium, which were identified as COPCs in surface soil (0 to 1 ft bgs) at Firing Site 6. Future construction workers were evaluated for exposures to the same COPCs in soil (0 to 10 ft bgs).

Potentially carcinogenic risks were calculated for both receptors and compared to the lower limit of USEPA's target risk range of 1.0E-06 to 1.0E-04. Table 6-12 shows that during the surface soil risk characterization of current and future site worker exposures, carcinogenic risks summed over all exposure routes (i.e., ingestion, dermal contact, and inhalation of airborne dusts and volatilized organics) exceeded 1.0E-06 for RDX (4.0E-06), 2,4,6-trinitrotoluene (1.2E-05), and chromium (2.2E-06). Dermal contact with 2,4,6-trinitrotoluene is the predominant contributor to the total cumulative cancer risk (1.8E-05) for this receptor. Therefore, RDX, 2,4,6-trinitrotoluene, and chromium were retained as carcinogenic COCs for the site worker.

Table 6-12 shows that only the cumulative pathway risk calculated for 2,4,6-trinitrotoluene (2.0E-06) exceeded USEPA's de minimis risk level of 1.0E-06 for future construction worker exposures to soil (0 to 10 ft bgs). The ingestion route of exposure contributed predominantly to the total cumulative cancer risk (2.8E-06) for this receptor. Therefore, 2,4,6-trinitrotoluene was retained as the only carcinogenic COC for the construction worker.

Noncarcinogenic risks (HIs) were calculated for both receptors and compared to USEPA's target HI of 1.0. Table 6-12 shows that during the surface soil risk characterization of current and future site worker exposures, HIs summed over all exposure routes (i.e., ingestion, dermal contact, and inhalation of airborne dusts and volatilized organics) exceeded 1.0 for 2,4,6-trinitrotoluene (2.5) and chromium (1.4). Dermal contact with 2,4,6-trinitrotoluene is the predominant contributor to the total HI (4.1) for this receptor. Therefore, 2,4,6-trinitrotoluene and chromium were retained as noncarcinogenic COCs for the site worker.

Table 6-12 shows that only the cumulative pathway HIs calculated for 2,4,6-trinitrotoluene (10) and chromium (5.8) exceeded USEPA's target criterion of 1.0 for future construction worker exposures to soil (0 to 10 ft bgs). The ingestion and dermal exposures to 2,4,6-trinitrotoluene, as

well as ingestion exposures to chromium, are the predominant COPC/exposure routes contributing to the total HI (16) for this receptor. Therefore, 2,4,6-trinitrotoluene and chromium were retained as noncarcinogenic COCs for the construction worker.

In summary, the following presents surface soil and soil COCs identified, by receptor, for the Firing Site 6, 7, 8, and 15 Area:

- Current and Future Site Workers (Surface Soil, 0 to 1 ft bgs)
  - RDX
  - 2,4,6-Trinitrotoluene
  - Chromium
- Future Construction Workers (Soil, 0 to 10 ft bgs)
  - 2,4,6-Trinitrotoluene
  - Chromium

6.7 UNCERTAINTY ANALYSIS

There are a number of factors that contribute uncertainty to the estimates of exposure and risk presented above. Uncertainties based upon derivation and use of toxicological values are inherent in each risk characterization. Some of these include:

- The use of animal data to predict potential human health effects.
- Extrapolation of experimental data obtained by exposing animals to high chemical doses to the likely outcome in humans following exposure to low chemical levels in the environment.
- The use of conservatively derived toxicological criteria.
- The lack of toxicity data for some chemicals evaluated in the risk characterization.
- Lack of toxicity criteria specific for evaluating the dermal route of exposure.

All of the above items are either utilized or evaluated in the risk assessment using methodologies that overestimate risks, thereby introducing health conservatism into the results. Additional uncertainties pertinent to the IAAAP HHRA and their impacts in over- or underestimating risk results for the evaluated exposure scenarios are discussed in the following subsections.

6.7.1 Uncertainties Associated with Biased Soil Sampling

The sampling scheme used to collect soil samples at the IAAAP sites was primarily based on obtaining biased samples from areas of historical operations, the locations likely to find PCOCs detected during previous investigations, and additional sampling locations selected in order to adequately determine nature and extent of contamination and to fulfill data requirements. Section 2.0 of the RI report discusses the various methods of biased sampling that was used to fully characterize nature and extent.

Because much of the sampling was biased toward areas of likely contamination, the EPCs calculated in this HHRA based on the biased datasets are likely to be higher than those that would be calculated based on a non-biased sampling strategy (e.g., random sampling, systematic random sampling from grid, etc.). Consequently, the human health risks are considered to be higher and more health-conservative. Therefore, applications of datasets based on biased sampling strategies have likely resulted in an over-estimation of the cancer and noncancer risks calculated in this HHRA.

Another potential source of risk assessment uncertainty relevant to sampling and analysis is that laboratory analysis of soil samples collected during the FUSRAP RI focused on the following five explosive compounds (i.e., out of the entire SW846 Method 8330 analytical suite): 1,3,5-trinitrobenzene, 2,4,6-trinitrotoluene, 2,4-dinitrotoluene, HMX, and RDX. These compounds were the focus of the FUSRAP RI, because the sampling and analysis plan (USACE, 2007) was developed based on existing results of previous investigations performed by JAYCOR (1992 – 1995) and by TN & Associates (2001 – 2002). Therefore, the explosives investigation for the FUSRAP RI focused only on the five aforementioned explosive PCOCs. Therefore, it is likely that any perceived data gap has not significantly resulted in an underestimation of risks in the HHRA.

6.7.2 Uncertainties Associated with the Data Evaluation and COPC Identification

Although the data evaluation process used to select COPCs adheres to established procedures and guidance, it also requires making decisions and developing assumptions on the basis of historical information, disposal records, process knowledge, and best professional judgment about the data. Uncertainties are associated with all such assumptions. The Region 9 Industrial PRGs used to screen analytes are also subject to uncertainty.

Another area of uncertainty involves the qualitative evaluation (and elimination from further consideration) of essential nutrients, many of which have no available toxicity values. In addition, the toxicity values used in the derivation of PRGs are subject to change as additional information becomes available from scientific research. These periodic changes in toxicity values may cause the PRG values to change as well.

Some unavoidable uncertainty is associated with the contaminant concentrations detected and reported by the analytical laboratory. The quality of the analytical data used in the risk assessment depends on the adequacy of the set of procedures that specifies how samples are selected and handled and how strictly these procedures are followed. QA/QC procedures within the laboratories are used to minimize uncertainties; however, sampling errors, laboratory analysis errors, and data analysis errors can occur.

Some current analytical methods are limited in their ability to achieve detection limits at or below risk-based screening levels (i.e., PRG concentrations). Under these circumstances, it is uncertain whether the true concentration is above or below the PRGs, which are protective of human health. When analytes are on the COPC list and have a mixture of detected and non-detected concentrations, risk calculations may be affected by these detection limits. Risks may be overestimated as a result of some sample concentrations being reported as non-detected at the method detection limit (MDL), which may be greater than the PRG concentration (when the actual concentration may be much smaller than the MDL). Risks may also be underestimated because some analytes that are not detected in any sample are removed from the COPC list. If the concentrations of these analytes are below the MDL but are above the PRG, the risk from these analytes would not be included in the risk assessment results.

The use of a large number of nondetects in a UCL calculation can also result in an underestimation of risk assuming the all MDLs are less than the PRG, but only if the EPC is not the maximum detected concentration. In the Tables 6-2 and 6-3 of the HHRA, a large number of nondetects (low frequency of detection) was noted for RDX (1 detect out of 12 samples analyzed) in the FS 3, 4, & 5 grouping, and for 2,4,6-trinitrotoluene in the FS-6, 7, 8, and 15 Area. Because the EPC for RDX in FS 3, 4, & 5 is based on the maximum detection, which was less than the PRG, the large number of nondetects had no impact on the COPC or risk

evaluations. However, the large number of nondetects could have underestimated the EPC for 2,4,6-trinitrotoluene at the FS-6, 7, 8, and 15 Area, which is based on the UCL. 2,4,6-trinitrotoluene was determined to be a risk driver and COC for the FS-6, 7, 8, and 15 Area, even with the UCL. Therefore, although risks may have been underestimated due to the number of nondetects in the 2,4,6-trinitrotoluene dataset, the final outcome of the HHRA for this COPC was not impacted, i.e., 2,4,6-trinitrotoluene being identified as a COC in the FS-6, 7, 8, and 15 Area soil.

Chromium was analyzed and detected in soil samples collected from IAAAP areas and was analyzed as total chromium. Uncertainty exists regarding the actual valence form of chromium that is predominant in site soils. However, according to ATSDR (1994), chromium compounds, mostly in the chromium(III) or chromium(VI) forms, are produced by the chemical industry and are used for chrome plating, the manufacture of dyes and pigments, leather tanning, and wood preserving. Smaller amounts are used in drilling muds, rust and corrosion inhibitors, textiles, and toner for copying machines. Because these potential sources are not consistent with historical site activities at the IAAAP, the total chromium PRG was used in the RI report data screening and in the HHRA evaluation of chromium as a COPC. The total chromium PRG assumes a 1:6 ratio of chromium VI to chromium III (EPA, 2004).

A final area of uncertainty is the comparisons of EPCs, rather than individual sample results, with USEPA Region 9 Industrial PRGs. The Region 9 PRGs were used in Section 4 for site characterization of contaminant nature and extent, while at the same time, being used to focus the HHRA on those chemicals that would undergo further evaluation as COPCs (Section 6.4). Individual sample data were compared to USEPA Region 9 Industrial PRGs in Section 4. For any chemical with at least one detected concentration exceeding the corresponding USEPA Region 9 Industrial PRG, an EPC was calculated in the HHRA. The EPC was then compared back to the USEPA Region 9 Industrial PRG, which is derived by USEPA Region 9 using conservative default exposure assumptions. Because USEPA Region 9 Industrial PRGs are derived based on conservative assumptions, it can be ascertained with a high level of confidence that a chemical with an EPC less than the USEPA Region 9 Industrial PRG, if carried through quantitative risk calculations, would not result in risks exceeding EPA's target risk criteria. Therefore, chemicals with EPCs less than USEPA Region 9 Industrial PRGs were eliminated from further evaluation in the site-specific HHRA. Those chemicals with EPCs greater than USEPA Region 9 Industrial PRGs were identified as COPCs for quantitative risk evaluation for IAAAP site workers and construction workers.

The concern over the applied COPC determination method is that risks could potentially be underestimated, because chemicals associated with individual sample concentrations exceeding screening values are eliminated, because corresponding EPCs are calculated to be less than screening values. Tables 6-2 and 6-3 show that RDX at the FS 3, 4, & 5 area is the only single point exceedance of a screening value (which is actually an OU#1 ROD RG established for groundwater protection) in which the chemical was not retained as a COPC for quantitative evaluation in the HHRA due to the EPC being less than the screening value. The EPC for RDX at the FS 3, 4, & 5 area (0.36 mg/kg) is less than the EPC for RDX at the FS-6, 7, 8 and 15 Area (76.9 mg/kg) by a factor of approximately 214. Total cumulative cancer and noncancer risks estimated for RDX exposures to the construction worker in the FS-6, 7, 8, and 15 Area were both less than USEPA's target risk criteria; therefore, no risk would be expected for the construction worker in the FS 3, 4, & 5 area. For the site worker in the FS-6, 7, 8, and 15 Area, a total cancer risk of 4.0E-06 was calculated due to RDX, which slightly exceeds USEPA's de minimis cancer risk criterion. The non-cancer HI calculated for site worker exposures to RDX at the FS-6, 7, 8,

and 15 Area was less than USEPA's noncancer risk criterion (HI = 1.0). Therefore, assuming a linear relationship between concentration and risk, the total risk expected for RDX exposures to the construction worker in the FS 3, 4, & 5 Area would be 1.9E-08. Therefore, this analysis indicates that the applied COPC determination method does not significantly underestimate total site risks.

6.7.3 Uncertainties Associated with the Exposure Assessment

Uncertainty is also introduced through the process of estimating representative exposure concentrations in the analyzed exposure media. Analytical results are used to calculate a mean concentration and the 95% UCL on the mean concentration. The lesser of the maximum detected concentration and the 95% UCL was used as the EPC for this HHRA.

Moderate uncertainty can be introduced in the data aggregation process for estimating a representative exposure concentration in the exposure media. USEPA's ProUCL program (version 4.0) applied statistical tests to determine the distribution that best describes the dataset for each chemical, within each area of concern. For each COPC, ProUCL then reports the 95% UCL associated with the distribution type that best describes the dataset of interest. Each COPC's 95% UCLs are calculated using both detected values and one-half of the reported detection limit for samples without a detected concentration. The EPC was determined to be the lesser of the maximum detected concentration versus the calculated 95% UCL. This method may moderately overestimate the exposure concentration. In addition, when the resulting individual contaminant risks are summed to provide a total ILCR or HI, the compounding conservatism of this method for estimating EPCs will likely result in an overestimation of the total risk.

Additionally, it is conservatively assumed that chemical concentrations detected under current site conditions will remain constant for evaluations of future exposure scenarios. In other words, the measured concentrations (and resulting EPCs) are not reduced by loss due to natural removal processes such as volatilization, leaching, and/or biodegradation. This assumption is a source of uncertainty that tends to overestimate future exposure concentrations.

Quantification of exposure provides an estimate of the chemical intake for various exposure pathways identified at the site. Several uncertainties associated with the various components of the exposure assessment include uncertainties about the exposure pathway equations, exposure parameters, land use scenarios, representative exposure concentrations, and sampling and analysis of the media.

For each primary exposure pathway chosen for analysis in this HHRA, assumptions are made concerning the exposure parameters (e.g., amount of contaminated media a receptor can be exposed to and intake rates for different routes of exposure) and the routes of exposure. In the absence of site-specific data, the assumptions used are consistent with USEPA-approved default values, which are assumed to be representative of potentially exposed populations. All contaminant exposures are assumed to be from site-related exposure media (i.e., no other sources contribute to the receptor's health risk).

Note that for the dermal contact with soil pathway, no exposure time is included in the equation. This is based on the assumption that the receptor may not bathe (i.e., to remove the soil in contact with the skin surface) for 24 hours following the initial exposure; therefore, the receptor is actually exposed to soil contaminants for 24 hr/day. This may overestimate the risk associated with dermal contact with soil. This fact is especially important since the dermal pathway is the major contributor to cancer and/or noncancer risks calculated for exposures to 2,4,6-trinitrotoluene and chromium for both the site worker and construction worker.

6.7.4 Uncertainties Associated with the Toxicity Assessment

The methodology used to develop a non-carcinogenic toxicity value (RfD or RfC) involves identifying a threshold level below which adverse health effects are not expected to occur. The RfD and RfC values are generally based on studies of the most sensitive animal species tested (unless adequate human data are available) and the most sensitive endpoint measured. Uncertainties exist in the experimental data set for such animal studies. These studies are used to derive the experimental exposure representing the highest dose level tested at which no adverse effects are demonstrated [i.e., the no-observed-adverse-effect level (NOAEL)]; in some cases, however, only a lowest-observed-adverse-effect level (LOAEL) is available. The RfD and/or RfC is derived from the NOAEL (or LOAEL) for the critical toxic effect by dividing the NOAEL (or LOAEL) by uncertainty factors. These factors usually are in multipliers of 10, with each factor representing a specific area of uncertainty in the extrapolation of the data. For example, an uncertainty factor of 100 is typically used when extrapolating animal studies to humans. Additional uncertainty factors are sometimes necessary when other experimental data limitations are found. Because of the large uncertainties (10 to 10,000) associated with some RfD or RfC toxicity values, exact safe levels of exposure for humans are not known. For non-carcinogenic effects, the amount of human variability in physical characteristics is important in determining the risks that can be expected at low exposures and in determining the NOAEL (USEPA 1989a).

The toxicological data (SFs and RfDs) for dose-response relationships of chemicals are frequently updated and revised, which can lead to overestimation or underestimation of risks. These values are often extrapolations from animals to humans, and this can also cause uncertainties in toxicity values because differences can exist in chemical absorption, metabolism, excretion, and toxic response between animals and humans.

USEPA considers differences in body weight, surface area, and pharmacokinetic relationships between animals and humans to minimize the potential to underestimate the dose-response relationship; as a result, more conservatism is usually incorporated into these steps. In particular, toxicity factors that have high uncertainties may change as new information is evaluated. Therefore, COPCs associated with high uncertainties in toxicity studies may be subject to regulatory change in the future. Finally, the toxicity of a contaminant may vary significantly with the chemical form present in the exposure medium. For example, risks from metals may be overestimated because they are conservatively assumed to be in their most toxic forms (e.g., chromium is assumed to be in the hexavalent form).

The carcinogenic potential of a chemical can be estimated through a two-part evaluation involving (1) a weight of evidence assessment to determine the likelihood that a chemical is a human carcinogen, and (2) a slope factor assessment to determine the quantitative dose-response relationship. Uncertainties occur with both assessments. Chemicals fall into one of five groups on the basis of WOE studies of humans and laboratory animals (USEPA 2005): (1) Group A – known human carcinogen; (2) Group B – probable human carcinogen based on limited human data or sufficient evidence in animals, but inadequate or no evidence in humans; (3) Group C – possible human carcinogens; (4) Group D – not classified as to human carcinogenicity; and (5) Group E – evidence of no carcinogenic effects in humans. Only one COPC (hexavalent chromium) identified at Firing Site 6 is a Group A carcinogen. All other COPCs are in the Group C and D categories.

The SF for a chemical is a plausible upper-bound estimate of the probability of a response per unit intake of a chemical over a lifetime. It is used to estimate an upper-bound lifetime

probability of an individual developing cancer as a result of exposure to a particular level of a potential carcinogen. The slope factor is derived by applying a mathematical model to extrapolate from a relatively high, administered dose to animals to the lower exposure levels expected for humans. The slope factor represents the 95% UCL on the linear component of the slope (generally the low-dose region) of the tumorigenic dose-response curve. A number of low-dose extrapolation models have been developed, and USEPA generally uses the linearized multi-stage model in the absence of adequate information to support other models. Therefore, methods used to derive SFs result in an overestimation of cancer risks in this HHRA.

Uncertainties exist regarding the toxicity criteria used to quantify cancer and noncancer risks for chromium. Chromium was identified as a soil COPC at the Firing Site 6, 7, 8, and 15 Area with concentrations having been detected at levels well above the corresponding Region 9 Industrial PRG (for total chromium) and background. Although chromium detections were analyzed and reported by the laboratory as total chromium, uncertainty exists regarding the actual valence state (e.g., 0, +3, or +6) of chromium in the soil at the Firing Site 6, 7, 8, and 15 Area. USEPA (2007) provides toxicity criteria for the hexavalent and trivalent states of chromium. During COPC identification, the total chromium PRG was applied for reasons stated in Sections 6.4.1 and 6.7.2. No toxicity criteria are available on IRIS (USEPA, 2007) for total chromium; however, an inhalation slope factor is provided for total chromium by the USEPA Region 9 Industrial PRG tables (USEPA, 2004). This inhalation slope factor corresponds to the inhalation unit risk for hexavalent chromium presented in IRIS (USEPA, 2007). Therefore, chromium was conservatively evaluated in the HHRA using toxicity criteria established by USEPA (2007) for hexavalent chromium. The hexavalent form is considered to be the more toxic form for chromium; therefore, risks calculated in the HHRA assuming that all chromium concentrations detected in site soils are hexavalent are likely to represent an overestimation of actual site risks.

Uncertainties are associated with the GI absorption factors used to modify the oral toxicity values to evaluate dermal toxicity. Many potential uncertainties are associated with the toxicity data used in this HHRA and can affect the risk, hazard, and COC determinations. In determining the dermal reference dose from the administered dose, USEPA RAGS Part E (2004) provides GI absorption factors for both the hexavalent and trivalent states of chromium. However, based on historical operations at the Firing Site 6, 7, 8, and 15 Area, neither the hexavalent nor trivalent form of chromium is considered to be the likely form of chromium present in site soils. Analytical results for chromium are reported as total chromium. Because USEPA RAGS Part E (2004) does not provide a GI absorption factor for total chromium, USEPA's default value of 100% was applied.

6.7.5 Uncertainties Associated with the Risk Characterization

Risk assessment, as a scientific activity, is subject to uncertainty. This is true even though the methodology used in this HHRA follows USEPA guidelines. As noted previously, the risk evaluation in this report is subject to uncertainty pertaining to sampling and analysis, selection of COPCs, exposure estimates, and availability and quality of toxicity data.

Uncertainties related to the summation of HQs and CRs across chemicals and pathways are a primary uncertainty in the risk characterization. In the absence of information on the toxicity of specific chemical mixtures, it is assumed that CRs and HQs are additive (i.e., cumulative) (USEPA 1989a). The limitations of this approach for non-carcinogens are (1) the effects of a mixture of chemicals are generally unknown – it is possible that the interactions could be synergistic, antagonistic, or additive; (2) the RfDs have different accuracy and precision and are

not based on the same severity or effect; and (3) HQ or intake summation is most properly applied to compounds that induce the same effects by the same mechanism. Therefore, the potential for occurrence of non-carcinogenic effects can be overestimated for chemicals that act by different mechanisms and on different target organs. In this HHRA, the identified noncarcinogenic COPCs affect different target organs and induce different systemic effects; therefore summation results in an overestimation of the HIs calculated for each receptor.

Even though summing HQs across all COPCs overestimates noncarcinogenic risks, the primary outcome of the risk characterization, i.e., the identification of COCs for each receptor, is not changed by not summing HQs. For the site worker, a review of Appendix C, Table 11 shows that not summing of HQs across COPCs would eliminate the total ingestion HI of 1.6 because all of the HQs estimated for that exposure route are less than 1.0. The HI for the dermal pathway would still be above 1.0 because the HQ alone for 2,4,6-trinitrotoluene is 2.3. Appendix C, Table 11 also shows that although none of the individual pathway HIs for chromium exceed 1.0, summing of chromium HIs across all pathways results in an HI of 1.4. Not summing HQs across COPCs for the site worker would result in 2,4,6-trinitrotoluene and chromium being identified as COCs for this receptor, which are the same COCs identified after summing noncarcinogenic risks. Therefore, not summing does not alter the outcome of the risk characterization for this receptor.

For the construction worker, Appendix C, Table 12, shows that the ingestion HQs for 2,4,6-trinitrotoluene and chromium exceed 1.0, and the dermal HQ for 2,4,6-trinitrotoluene also exceeds 1.0. Not summing HQs across COPCs for the site worker would result in 2,4,6-trinitrotoluene and chromium being identified as COCs for this receptor, which are the same COCs identified after summing noncarcinogenic risks. Therefore, not summing does not alter the outcome of the risk characterization for this receptor.

Limitations of the additive risk approach for multiple carcinogens are (1) the chemical-specific slope factors represent the upper 95th percentile estimate of potency; therefore, summing individual risks can result in an excessively conservative estimate of total lifetime cancer risk; and (2) the target organs of multiple carcinogens may be different, so the risks would not be additive. In the absence of data, additivity for CRs and HQs is assumed for this HHRA. However, because total risks and HIs are usually driven by a few chemicals, segregation of risks and HIs by target organ would most likely not have resulted in significantly different outcomes.

Additional uncertainty can be associated with the method of selection of COCs. For this HHRA, COCs were selected for the evaluated soil strata as chemicals with individual CRs $\geq$ 1.0E-06 and/or individual HQs $\geq$ 1.0 for any medium/land use scenario.

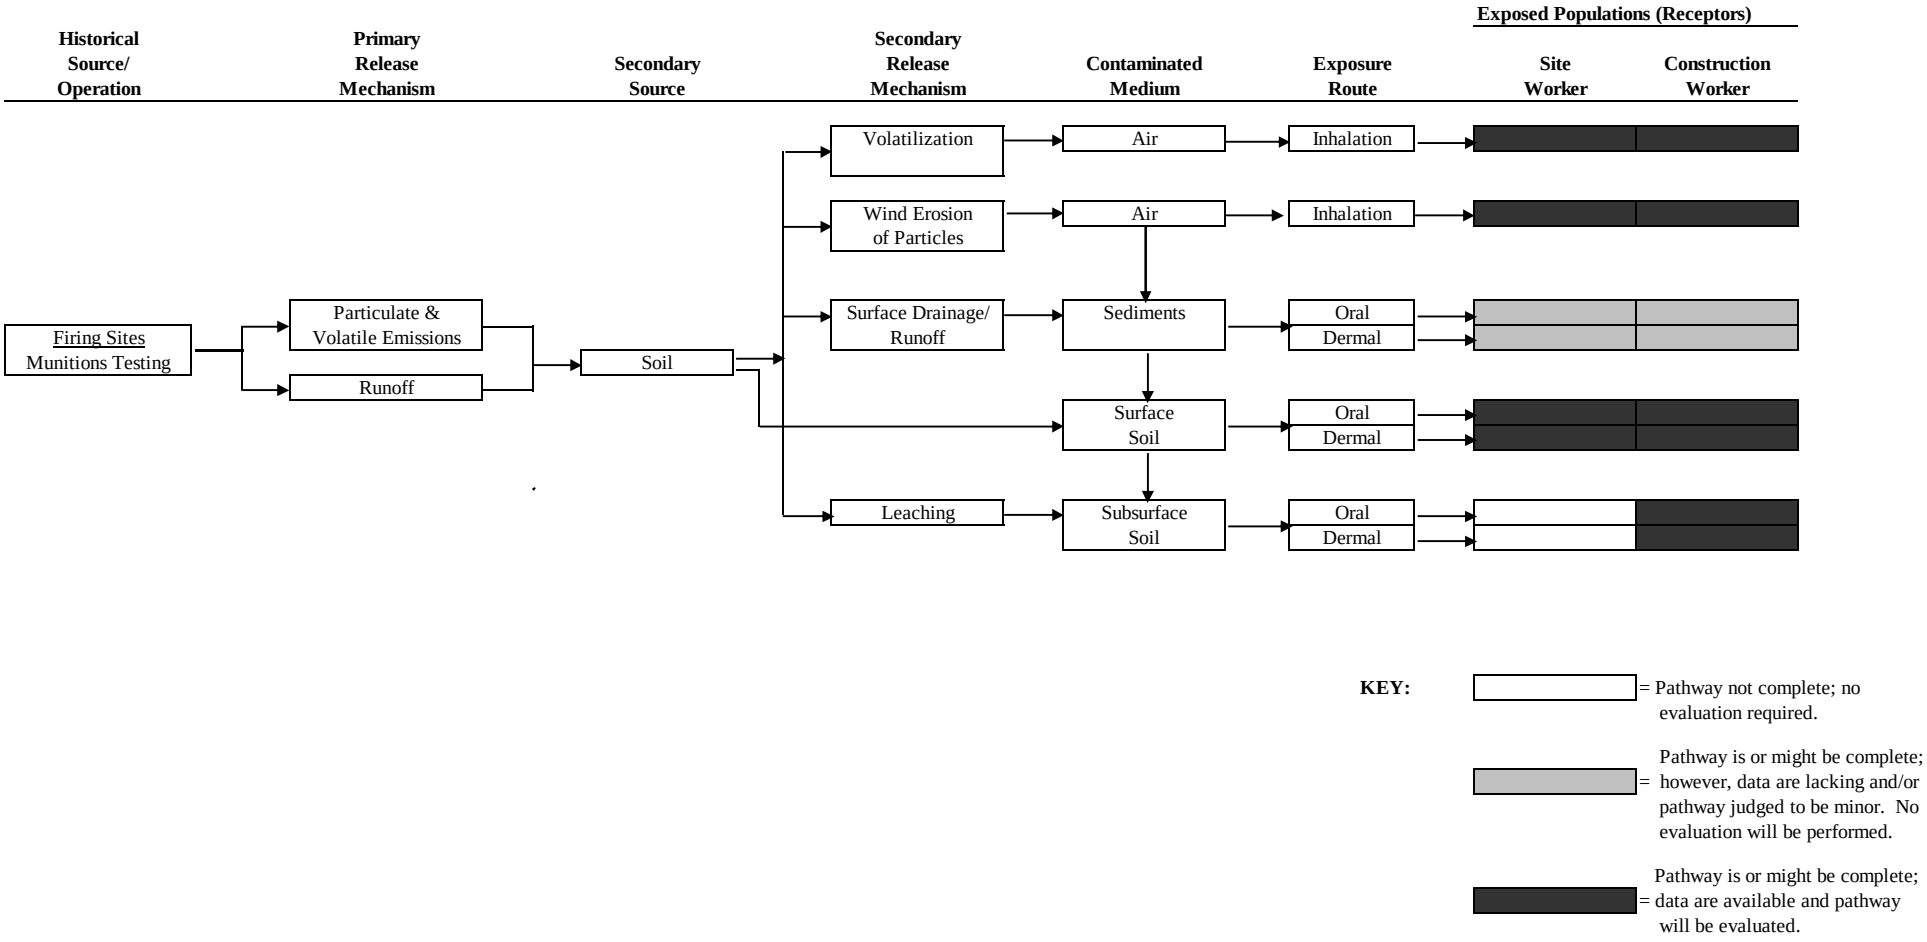

Figure 6-1. Human Health Baseline Risk Assessment Conceptual Site Model for the IAAAP Area Evaluations.

7.0 STREAMLINED ECOLOGICAL RISK ASSESSMENT

An ERA was performed as part of the BRA in support of the FUSRAP RI. The purpose of the ERA is to assess the potential for adverse effects to ecological receptors resulting from exposure to chemicals at the FS Area (collectively), Yard C, and Yard G in the absence of remediation at each site. Yards E and F and the Area West of Line 5B were only investigated for radiological constituents and not for chemicals; therefore, these sites were not evaluated in ERA as discussed in Section 7.1. The ERA distinguishes between sites that pose negligible risk and require NFA from sites and chemicals having the potential to cause ecological risks. Typically in the ERA process, either a screening-level or baseline ecological risk assessment would be conducted for the sites included in this RI Report. However, given the comprehensive approach provided in the BERA (USACE, 2004a), USACE St. Louis District believes a streamlined ERA will expedite decision-making in a manner that is consistent with the BERA (USACE, 2004a). The methodology for the streamlined ERA is discussed in Section 7.1, while the results and uncertainties are presented in Sections 7.2 and 7.3, respectively.

In addition to adopting the BERA (USACE, 2004a) as the basis for the streamlined ERA approach, USACE St. Louis District has also incorporated the ecological approach discussed in the *Explanation of Significant Differences for the Interim Action Record of Decision (IROD) Soils Operable Unit (OU-1) Addition of Environmental Protectiveness to the Remedy and Transfer of Sites from OU-4 to OU-1 for Iowa Army Ammunition Plant Middletown, IA* (Eco ESD) (Tetra Tech, 2007). Both the IROD and Eco ESD represent agreements among the Army, IRP, and USEPA Region 7 that establish requirements and procedures related to investigation and remediation activities being implemented at IAAAP by the Army. Activities being conducted as part of the FUSRAP RI are not bound to the IROD and Eco ESD; however, USACE St. Louis District has incorporated the ecological technical approaches and methodologies presented therein into this streamlined ERA in order to promote consistency between Army and USACE St. Louis District FUSRAP activities. Prior to adopting the ecological approaches contained in the BERA and Eco ESD, both documents were reviewed for content, technical approach/methodology, and results. Both the BERA (USACE, 2004a) and Eco ESD (Tetra Tech, 2007) were found to be a technically defensible evaluation of ecological risk at the IAAAP. More specifically, the following elements of these documents were utilized to determine the basis for this streamlined ERA for the RI:

- The terrestrial receptors evaluated in the BERA (Short-Tailed Shrew *[Peromyscus leoucopus],* White-Footed Mouse *[Blarina brevicauda],* and Indiana Bat *[Myotis sodalis]*), with the focus now shifted toward protection of the Indiana Bat in accordance with Appendix M of the BERA and the Eco ESD;
- The use of EPCs for determining ecological risks associated with evaluated areas, as were applied in the BERA;
- The BERA Toxicity Reference Values (i.e., Lowest Observed Adverse Effects Levels [LOAELs] and No Observed Adverse Effects Levels [NOAELs]);
- The soil-to-insect Bioaccumulation Factors (BAFs) described in Appendix M of the BERA used for updating Ecological Critical Concentrations (Eco CCs) from those based on soil-to-earthworm BAFs that were originally used in the BERA;
- The calculation methodologies/equations presented in the BERA, Appendix M for determining Eco CCs (i.e., for updating from the soil-to-earthworm uptake model to the soil-

to-insect uptake model), and application of the Eco CCs in a manner consistent with the performance standards established in the Eco ESD (as discussed in Section 7.1 of this streamlined ERA);

- Indiana bat exposure parameters; and
- The quantitative comparison of the site area and the 70-acre foraging area of the juvenile Indiana Bat, (i.e., the "area use" factor [AUF] as introduced into Eco CC calculations in the BERA and Eco ESD).

Although there are no disagreements with the BERA (USACE, 2004a) methodology and findings, USACE St. Louis District has acknowledged some uncertainties regarding the BERA and its application to the streamlined ERA. These uncertainties are documented in Section 7.3 of this report. Additionally, based on a review of Appendix M of the BERA (BERA Closeout) (USACE, 2004a), USACE St Louis District acknowledges that existing correspondence post-dating the 2004 BERA publication date indicates that subsequent BERA issues were being addressed, which may or may not have resulted in further revisions to the BERA (USACE, 2004a). However, USACE St Louis District accepts the BERA (USACE, 2004a) as prepared by USACE Omaha District in 2004 and has adopted the methodologies, assumptions, and findings therein, as the basis for the technical approach of the streamlined ERA conducted in support of this FUSRAP RI Report.

7.1 APPROACH

This section presents an overview of the procedures for conducting the streamlined ERA. The approach was designed to be consistent with the overall approach and conclusions presented in the BERA (USACE, 2004a). The BERA (USACE, 2004a) was prepared as a site-wide evaluation of areas of concern by the U.S. Army at the IAAAP. The streamlined ERA compared *exposure point concentrations* (EPCs) for each FUSRAP area against the existing ecological *critical concentrations* (Eco CCs) presented in the BERA (USACE, 2004a). Ecological EPCs were derived using the methodology discussed in Section 6.3.4 of the HHRA. Eco CCs were derived in the BERA (USACE, 2004a) for the following terrestrial receptors: the white-footed mouse, short-tailed shrew, and the Indiana Bat. However, based on the Eco ESD (Tetra Tech, 2007), as well as the BERA (Appendix M, Attachments F and G), the Indiana Bat has become the only terrestrial receptor for which Eco CCs need to be developed. As a result, the streamlined ERA calculated Eco CCs for just the Indiana bat.

Eco CCs for the Indiana bat were originally derived under the assumption that Indiana bats ingest earthworms which have been impacted by site soils. Therefore, the original Eco CCs presented in the BERA (USACE, 2004a) were derived using BAFs based on earthworm ingestion of soil. Based on Appendix B, Technical Memo 5 of the BERA (USACE, 2004a), use of the soil-to-earthworm BAF in the BERA to calculate Eco CCs was overly conservative because the diet of the Indiana Bat does not include earthworms. Rather, a major portion of the bat's dietary intake consists of flying insects. Therefore, BAFs based on earthworms that have bioaccumulated chemicals from soil were subsequently replaced with BAFs based on insects that have bioaccumulated contaminants from soil, in accordance with the two following attachments presented in Appendix M of the BERA (USACE, 2004a):

- Attachment F: *Technical Approach to Calculating Ecological Risk, U.S. Army (January 20, 2006) – Path Forward to Ecological Risk Issues.*

- Attachment G: *Technical Memorandum (February 15, 2006), Tetra Tech – Possible Demolition Ecological Risk Calculation.*

The recalculated Indiana Bat Eco CCs were officially adopted as part of the remedy to the Interim ROD (United States Army Environmental Center 1997) in the Eco ESD (Tetra Tech, Inc. [Tetra Tech], 2007). The chemicals for which soil Eco CCs were derived in the BERA (USACE, 2004a) were those determined, through calculations of ecological hazard quotients (HQs), to be associated with potentially unacceptable risks to terrestrial receptors. Application of the Eco CCs in the streamlined ERA reflects acceptance of the HQs that were calculated and are presented in the BERA, as well as the methodologies and assumptions used in those calculations.

Eco CCs were first compared to individual sample results for each area. If there was at least one detected concentration exceeding a corresponding Eco CC, then an EPC was calculated for the exceeding chemical(s) for that area, and that area was retained for further evaluation in the streamlined ERA. If there were no exceedances of an Eco CC for an area, then that area was eliminated from further evaluation. Single point exceedances of Eco CCs were observed for Firing Sites, Yard C, and Yard G soils; therefore, these areas were retained for further evaluation in the streamlined ERA (i.e., calculations of EPCs and subsequent comparisons with Eco CCs).

In the streamlined ERA, if EPCs for a FUSRAP area were below respective Eco CCs, then no further evaluation was warranted regarding ecological concerns in that area. If EPCs for an area were above respective Eco CCs, then additional analysis of the data is warranted during the next phase of the project, (i.e., during preparation of the FS). The comparison of the EPCs to Eco CCs was a key line-of-evidence in the BERA (USACE, 2004a) for the terrestrial environment.

The streamlined ERA approach includes the following methods and assumptions:

1. The Eco ESD (Tetra Tech, 2007) amends the IROD for OU-1 soils, which was prepared for and signed by AEC. USACE St. Louis District is not a signatory of the IROD for OU-1 soils or the Eco ESD and is therefore, not bound by the requirements and standards established therein. However, in order to maintain consistency with AEC's ecological approach at IAAAP, USACE St. Louis District has adopted the methods and assumptions established in the Eco ESD until such time that a ROD is developed and signed for the FUSRAP sites.
2. Where the BERA (USACE, 2004a) considered HQs based on the LOAEL and the NOAEL, the Eco ESD (Tetra Tech, 2007a) established a performance standard for ecological soil remediation based on the more conservative of the following two standards which are used to calculate Indiana bat CCs in this streamlined ERA:
    - HQ of less than 10 for HQ based on NOAEL
    - HQ of less than 1 for HQ based on LOAEL
3. For each evaluated chemical, the lower of the two Indiana Bat CCs (i.e., the lower of the bat CCs derived based on a NOAEL-based HQ of 10 versus a LOAEL-based HQ of 1) was selected as the Eco CC used in comparisons with soil data in this ecological evaluation. If the lower of the two bat CCs was less than the corresponding BERA background value (i.e., for metals), then the other bat CC was selected to be the Eco CC. If both bat CCs were less than the BERA background value, then the background value was selected as the surrogate Eco CC.

4. For consistency with BERA (USACE, 2004a) methodology, the background value used in the ecological evaluations for any chemical was that value equivalent to the mean concentration of the background dataset plus two times the standard deviation.
5. During evaluations to determine the potential for ecological risk, Eco CCs were initially compared to soil EPCs calculated over the depth of the entire soil column for which data are available. For the Firing Sites, Eco CCs were compared to soil data acquired for the 0 to 6 ft bgs depth interval. Based on occurrence and distribution of detected chemicals throughout the evaluated soil column at the Firing Sites, Eco CC comparisons were made against metals and explosives data for soils within the 0 to 1 ft bgs depth interval, and against only metals data for soils within the 1 to 6 ft bgs depth interval. For Yards C and G, Eco CCs were compared to soil data acquired for only the 0 to 0.5 ft bgs depth interval.
6. Eco CCs have been derived as part of this Streamlined ERA for hexavalent and trivalent chromium (3,240 mg/kg and 184,679 mg/kg, respectively) because total chromium was detected in soil samples at a high frequency in the evaluated FUSRAP areas, and because values were not derived as part of the BERA (USACE, 2004a). Derivation of the chromium Eco CCs, which was based on the methodology presented in the BERA (USACE, 2004a) and performance standards established in the Eco ESD (Tetra Tech, 2007) (see item #2 above), is discussed in Section 7.1.1.
7. For any given area, exceedance of a soil Eco CC by an EPC will be further evaluated for potential remediation in the FS.
8. For evaluations of ecological risk in the FS, it will be assumed that the planned land use at the FUSRAP sites will continue to be "industrial" in nature. Continued use of these areas for military operations could serve as a deterrent to use by the Indiana bats. In addition, and particularly for the Firing Sites, continued firing is expected. As a result, the areas with exceedances could become contaminated again if remediation were to occur.

7.1.1 Derivation of Ecological Critical Concentrations for Chromium

Chromium was detected frequently in soil samples collected from the evaluated FUSRAP areas; however, no Eco CCs were derived for chromium in the BERA (USACE, 2004a). Therefore, chromium Eco CCs were derived for the Indiana bat as part of the Streamlined ERA in order to determine the potential for ecological risks to individual receptors. Because chromium speciation was not determined during the RI, Eco CCs have been derived for two valence states of chromium: hexavalent and trivalent chromium. To calculate the critical concentrations for chromium for the Indiana bat in the terrestrial environment, the following equation, consistent with the methodology presented in the BERA (USACE, 2004a), was used:

$$CC_{soil} = \frac{TRV \times BW_{bat} \times HQ}{IR_{bat}(food) \times P_{terr\text{-}inv} \times BAF_{terr\text{-}inv} \times AUF}$$

where:

CC_{soil}	=	Critical concentration of the COPEC in soil, mg/kg
TRV	=	Toxicity Reference value (NOAEL or LOAEL-based), (mg/kgBW/day)
BW_{bat}	=	Body weight of the Indiana bat, 0.0072 kg
HQ	=	Hazard Quotient of 10 with a NOAEL-based TRV and 1 with a LOAEL-based TRV, unitless

$IR_{bat\ (food)}$ = Ingestion rate of food, 0.0025 kg/d

$P_{terr-inv}$ = Fraction of insect ingested as proportion of total diet, unitless, ($P_{terr-inv}$ =1 as insect is primary food item of the Indiana bat)

$BAF_{terr-inv}$ = Bioaccumulation factor (soil-to-terrestrial invertebrate), (mg/kg wet weight tissue)/(mg/kg dry weight soil)

AUF = Area use factor, unitless, (ratio of the organism's home range to the site area; AUF =1 for the sites evaluated in this streamlined ERA)

The trivalent chromium and hexavalent chromium NOAEL and LOAEL-based CCs based on the calculation are presented in Table 7-1.

Table 7-1. Indiana Bat CCs for Chromium, Iowa Army Ammunition Plant, Iowa

Chromium Species	NOAEL-based CC (mg/kg)[a]	LOAEL-based CC (mg/kg)[b]	Selected IAAAP Eco CC (mg/kg)[c]
Trivalent Chromium	184,679	184,679	184,679
Hexavalent Chromium	16,200	3,240	3,240

[a]The NOAEL-based CC is the concentration in soil that results in an HQ of 10 when the NOAEL is used as the TRV.
[b]The LOAEL-based CC is the concentration in soil that results in an HQ of 1 when the LOAEL is used as the TRV.
[c]The selected value is the lower of NOAEL-based CC or the LOAEL-based CC.

Consistent with the methodology presented in the BERA (Appendix M, Attachment G - "Possible Demolition Site Ecological Risk Calculation Technical Memorandum" (Tetra Tech 2006)), soil to insect BAFs presented in the *Development of Terrestrial Exposure and Bioaccumulation Information for the Army Risk Assessment Modeling System (ARAMs)* (USACHPPM, 2004) document, along with the soil insect data from Savanna Army Depot presented in Table 3-3 of the BERA (USACE, 2004a) were used to develop the chromium BAFs. These BAFs are presented in Table 7-2 and 0.036 was used to derive the chromium CCs in Table 7-1.

Table 7-2. Chromium Soil to Insect BAFs, Iowa Army Ammunition Plant, Iowa

BAFs					
Median BAFs[1]			Mean BAFs		
Actual Values[2]	Geometric Mean	Wet Weight BAF[3]	Actual Values[2]	Geometric Mean	Wet Weight BAF[3]
0.0651	0.076	0.024	0.144	0.115	0.036
0.0846			0.137		
0.1548			0.304		
0.0506			0.057		
0.058			**0.058**		

[1] The median BAF values were not used to calculate chromium (either trivalent or hexavalent chromium) CCs, but are presented for comparison purposes.
[2] The actual values in bold are SVDA BAFs presented in Table 3-3 of the Draft Final BERA for IAAAP (MWH 2004). The SVDA BAFs were calculated by dividing the average concentration in insects by the average concentration in soil and were converted from wet weight to dry weight by dividing the wet weight BAF by 0.31, which is the percent solids for grasshoppers and crickets (Tetra Tech 2006). The remaining actual values were BAFs from the Class Insecta presented in Table 4-5 (USACHPPM 2004).
[3] The dry weight BAF was converted to wet weight tissue/dry weight soil by multiplying by 0.31 (Tetra Tech 2006).

Although a chromium TRV value was used in the Draft Final BERA (USACE, 2004a) the chromium TRV used in the BERA was selected from a 1975 study (as cited in Sample, Opresko, and Suter 1996). To capture more recently available research, EPA's Ecological Soil Screening Levels (Eco-SSLs) were reviewed to determine appropriate TRVs for trivalent chromium and hexavalent chromium for the Indiana bat. Eco-SSLs were developed by a workgroup consisting of Federal, state, consulting, industry, and academic participants led by USEPA and are accepted for use at a national level. Eco-SSLs (USEPA, 2005) provide thorough, peer-reviewed documentation of toxicity benchmark data for common Superfund site contaminants. Eco-SSLs often provide more recent or improved TRVs from which to select a value and were adopted for use in the chromium CC derivation. TRVs (i.e., NOAEL and LOAEL values) for trivalent chromium and hexavalent chromium used to derive the CC are presented in Table 7-3.

Table 7-3. Indiana Bat TRVs Selected for Chromium CC Calculations, Iowa Army Ammunition Plant, Iowa

Chromium Valence	Test Organism	Effect	Reference Study and Date	Chronic NOAEL (mg/kg/day)	Chronic LOAEL (mg/kg/day)
Trivalent Chromium	Mouse	Reproduction	Elbetieha and Al-Hamood (1997)*	228	2,280
Hexavalent Chromium	Rat	Reproduction	Chowdhury and Mitra (1995)*	20	40

*As cited in USEPA 2008.

7.2 RESULTS

Soil EPCs were developed for each chemical in the FS Area (collectively), Yard C and Yard G exhibiting at least one analytical result above the appropriate Eco CC as presented in Section 6 of the BERA (USACE, 2004a). Table 7-4 provides the results of these comparisons and indicates that Eco CC exceedances occurred at all three areas. The exceedances were for explosives and metals. As stated in the previous section, the exceedances require further evaluation to determine if remediation is warranted. A point-by-point evaluation was conducted (Sections 7.2.1 through 7.2.3) to determine how many individual sample locations exceeded the Eco CCs and the locations of the individual exceedances. Figures 7-1 through 7-4, which are used in the evaluations in Sections 7.2.1 through 7.2.3, have been prepared for each chemical with an EPC that exceeds the corresponding Eco CC in an area or group of areas shown on the figures. Each figure shows individual sample concentrations of a chemical within each area that exceed the Eco CC. Those chemicals with EPCs below corresponding Eco CCs (Table 7-4) do not pose unacceptable ecological risks.

Table 7-4. Ecological Evaluation of Indiana Bat Exposures to Soil[1] Firing Sites, Yard C, and Yard G

Chemical	Critical Concentration[2] (mg/kg)	EPC (mg/kg)	EPC/Critical Concentration Ratio[3]
Firing Sites			
2,4,6-Trinitrotoluene	3.55	214.2	**60.3**
Selenium	1.61	9.028	**5.6**
RDX	25.6	21.32	0.931
Antimony	1161	29.45	0.83
Mercury	1.86	1.146	0.62
Copper	2444.73	1110	0.454
Thallium	19.05	7.876	0.413
Nickel	3097	1058	0.34
Chromium[4]	3240	708.9	0.22
HMX	15.2	3.2	0.21
Silver	91.7	11.59	0.13
Barium	2520	231.8	0.092
Arsenic	156.1	7.344	0.047
Manganese	21987	722.1	0.033
Cobalt	743	9.843	0.013
Yard C			
HMX	15.2	42.99	**2.83**
Barium	2520	331.5	0.13
Arsenic	156.1	9.221	0.059
Cobalt	743	11.83	0.016
Yard G			
HMX	15.2	46.55	**3.06**
Mercury	1.86	0.843	0.45

[1]For evaluation in the FUSRAP RI Report, surface and subsurface concentrations measured at all depths were incorporated into calculations of EPCs. For the Firing Sites, Yard C, and Yard G, surface soil data comprised 95%, 100%, and 100%, respectively, of the data sets. At the Firing Sites, surface soil depth intervals sampled included 0 to 0.5 ft, 0.5 to 1.0 ft, and 0 to 1.0 ft, and subsurface intervals included 2.0 to 4.0 ft and 4.0 to 6.0 ft. Surface soil was sampled from only the 0 to 0.5 ft depth at Yards C and G. Further evaluations of Eco CC exceedances in the FS will include only surface soil data, which is consistent with Indiana bat exposures.

[2]Based on CCs derived in USACE, 2004a, Baseline Ecological Risk Assessment, Iowa Army Ammunition Plant, revised to incorporate soil-to-insect rather than soil-to-earthworm BAFs.

[3] Bolded ratios/shaded rows indicate chemicals with ratios exceeding 1.0, indicating a potential for risk to terrestrial receptors.

[4] Eco CC for hexavalent chromium. There were no exceedances for trivalent chromium.

7.2.1 Yard C Results

Constructed during World War II, Yard C has subsequently been used by both AEC and the Army and is currently in use by the Army. Yard C, which is 301 acres in size, consists primarily of 43 earthen igloos that are arranged in eight rows such that igloos are adjacent to a rail line and access road. The EPC for HMX exceeded the Eco CC at Yard C (Table 7-4). Only 1 of 26 individual samples exceeded the Eco CC for HMX (Figure 7-1). The single exceedance of the HMX Eco CC occurred at location IAAP96889 (0 – 0.5 ft depth) and will be further evaluated for potential remediation in the FS.

7.2.2 Yard G Results

Yard G consists of a small, relatively flat area around the igloo loading docks and associated driveways, and then drops steeply from the edge of the access road towards Long Creek at the bottom of the valley. Yard G, which is 259 acres in size, is currently in use by the Army. The EPC for HMX exceeded the Eco CC at Yard G (Table 7-4). However, only 1 of 13 individual

samples exceeded the Eco CC for HMX (Figure 7-2). The single exceedance of the HMX Eco CC occurred at location IAAP96872 (0 – 0.5 ft depth) and will be further evaluated for potential remediation in the FS.

7.2.3 Firing Sites Results

The Firing Sites Area is a fenced site that encompasses 450 acres and is approximately one mile from the nearest installation boundary. The Firing Sites Area is currently in use by the Army. The site contains administrative buildings and testing areas. FS Area facilities are designated FS-1 through FS-15. The EPCs for 2,4,6-TNT and selenium exceeded the Eco CCs at the Firing Sites Area (Table 7-4).

2,4,6-TNT exceeded the Eco CC in the Firing Sites at four locations, all of which are located within the northeast portion of the FS-6, 7, 8, and 15 Area (Figure 7-3), which is one of the smaller firing site areas at 4.2 acres. Selenium EPC exceedances of the Eco CC occurred at one location in the FS-6 area, two locations in the FS 1 & 2 area, two locations in FS-12, and one location in FS-14 (Figure 7-4). The locations exhibiting Eco CC exceedances will be further evaluated for potential remediation in the FS.

7.3 UNCERTAINTIES

Uncertainty is inherent in the selection of key input parameters and in every step of the risk assessment process. The results of the streamlined ERA may be understood only in light of the assumptions and methods used in the evaluation. This streamlined ERA follows methods previously presented in the BERA (USACE, 2004a); however, there are five key uncertainties associated with the streamlined ERA that are discussed below.

First, the Eco CC comparison was conducted for chemicals in each exposure area using the list of Eco CCs derived in the BERA (USACE, 2004a). Eco CCs (originally provided in Table 6-1a of the BERA (USACE, 2004a) and subsequently revised in this streamlined ERA) were not derived previously for some of the chemicals detected in the sites evaluated in the streamlined ERA. However, due to the prevalence of chromium detected in the evaluated sites, Eco CCs were derived for chromium in this streamlined ERA).

The absence of CCs for some chemicals could potentially result in an underestimation in ecological risk. Table 7-5 lists those chemicals for which Eco CCs were not calculated and presents an evaluation of prevalence and comparisons to background for these chemicals, which consist of explosives and metals. Prevalence was evaluated for all chemicals through calculations of frequencies of detections (FODs). FODs can be directly correlated to the probability that a receptor can become exposed to site contaminants while roaming and foraging over the area of concern. Explosives were detected in soil samples collected from the Firing Sites and Yard C at frequencies ranging from 3% to 10%. Given the large areas of these sites (450 and 301 acres, respectively) and the relatively low FODs, the probability for exposure to an individual receptor is considered to be low. Therefore, the absence of an Eco CC comparison for detected explosives in Firing Sites and Yard C soils is not expected to result in an underestimation of ecological risk.

Table 7-5. Evaluations of Detected Chemicals without Critical Concentrations at Firing Sites, Yard C, and Yard G

Chemical	Number of Detections	Total Number of Samples Analyzed	% FOD[1]	EPC[2] (mg/kg)	Background Value[3] (mg/kg)	EPC/ Background Value Ratio[4]

[1] %FOD = Frequency of detection expressed as percent of detections over total number of samples analyzed. %FOD was determined for all chemicals in Table 7-2.

[2] EPCs = Exposure point concentrations. EPCs were determined for only inorganics that are not macronutrients. EPCs are calculated for comparisons with background values.

[3] Background values were obtained from BERA (USACE, 2004a) and represent the mean concentration plus 2 times the standard deviation. Background values were established in the BERA (USACE, 2004a) for only inorganics that are not macronutrients. No background value was established for boron in the BERA (USACE, 2004a).

[4] EPC/Background value ratio less than 1.0 indicates EPC is less than the background value (shaded).

[5] --- = EPC not calculated for organic or macronutrient inorganic because no comparisons to background value is made. No background value is available for boron.

Metals without Eco CCs were detected in all three areas (Firing Sites, Yard C, and Yard G) evaluated in this Streamlined ERA. Table 7-5 shows relatively high FODs for these metals across all three sites, ranging from 47% to 100%, with most metals being detected at frequencies above 90%. EPCs were calculated for the metals and compared to background values derived in the BERA (USACE, 2004a). All metals EPCs, except the EPC calculated for iron at the Firing Sites, are less than background, as indicated by EPC/background value ratios less than 1.0. The

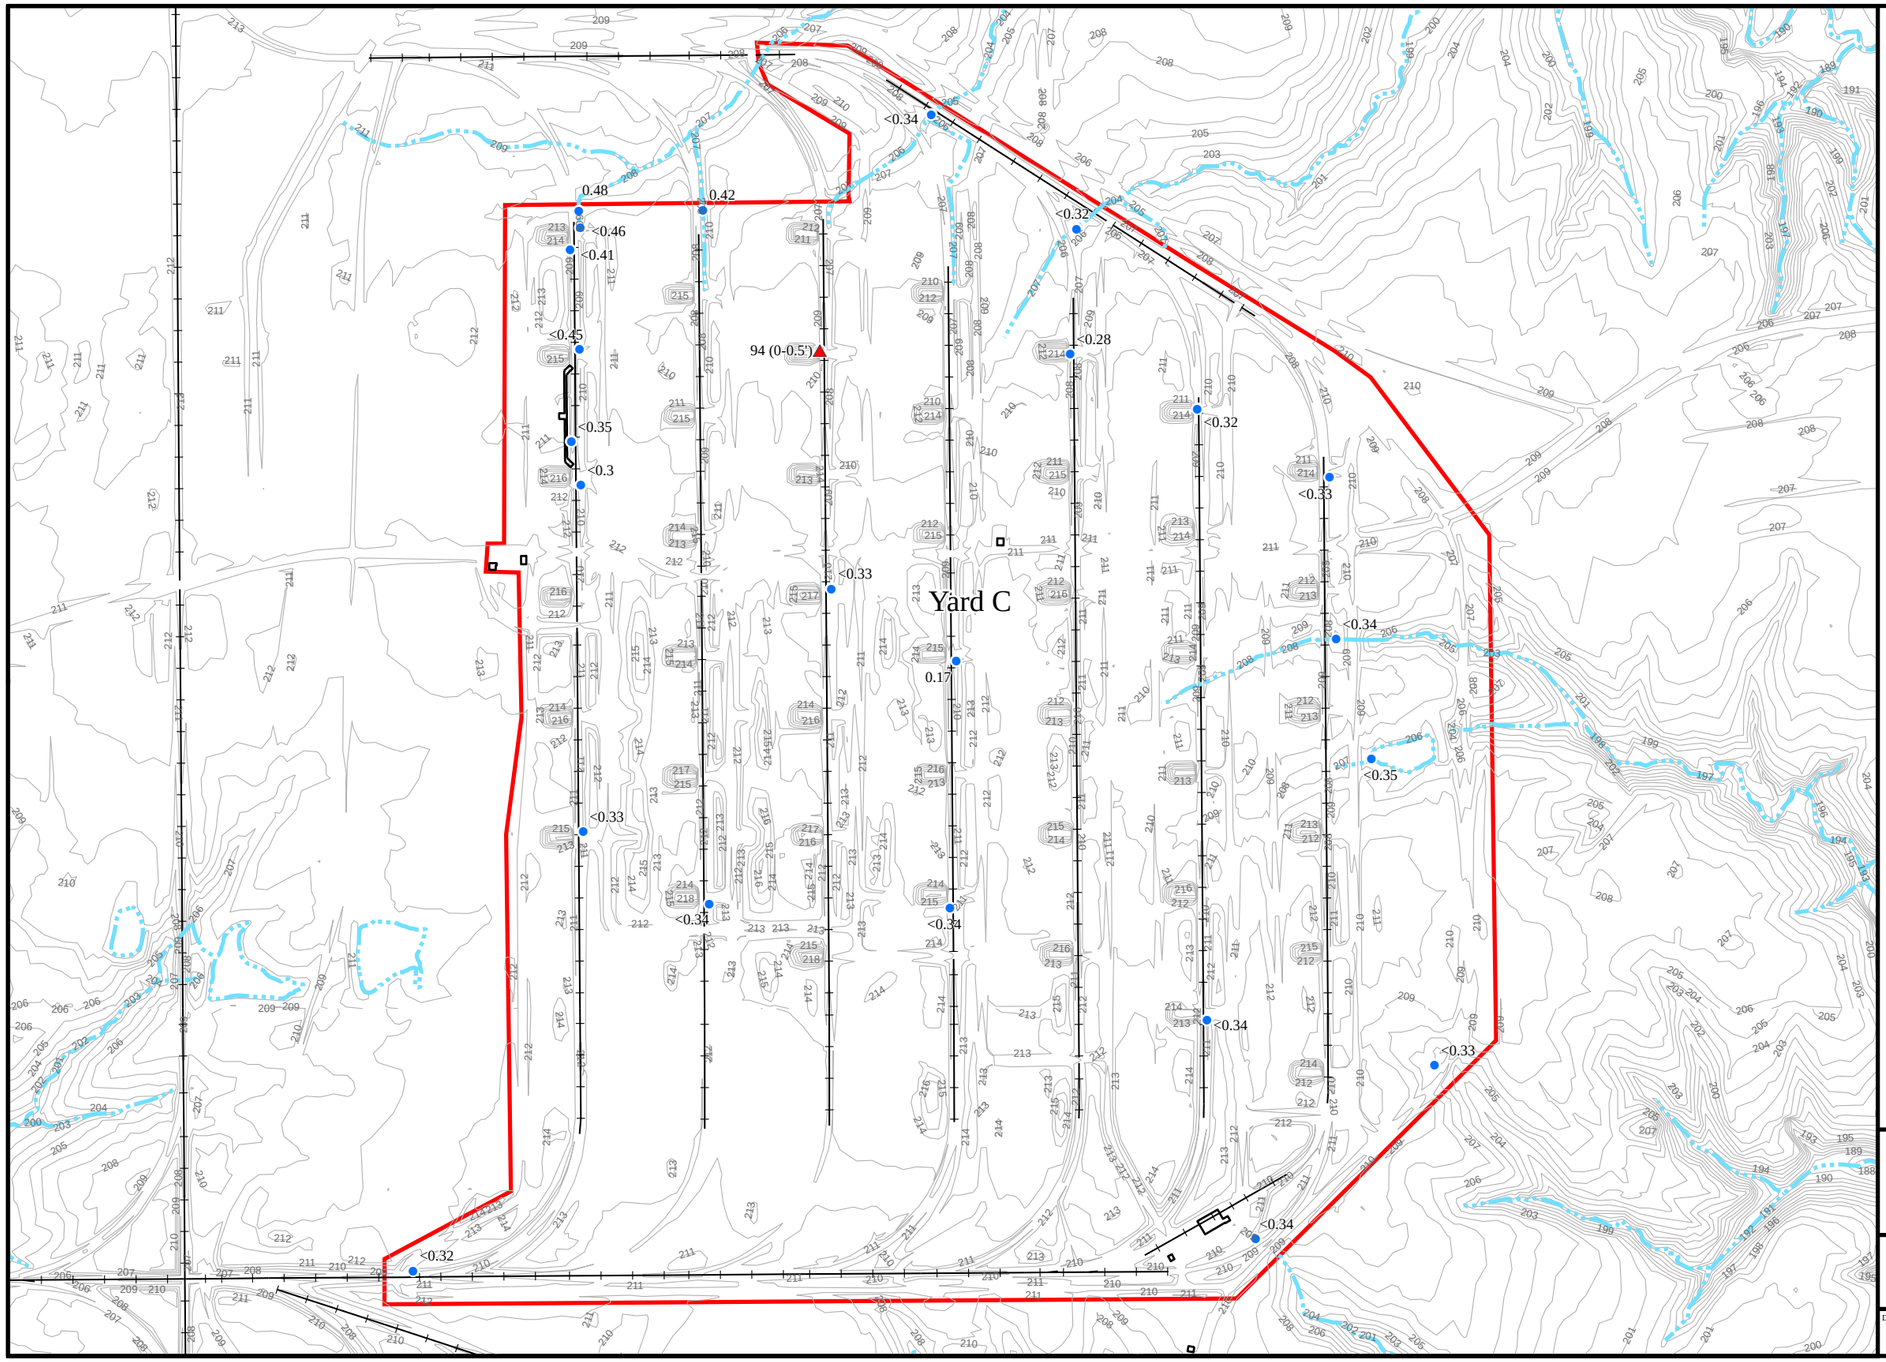
iron EPC is roughly equivalent to background with a ratio of 1.03. For the remaining metals detected in all three areas for which no Eco CCs have been derived, it is likely that risks to ecological receptors are not underestimated because those metals are present at levels consistent with naturally occurring background.

Second, Table 7-6 shows individual sample concentrations (with sample IDs in parentheses) for chemicals detected at the Firing Sites that exceed Eco CCs, for which corresponding EPCs (i.e., 95% UCLs) were determined to be less than the Eco CCs. Only chemicals detected at the Firing Sites are presented in Table 7-6 because none of the chemicals detected in Yards C and G, with EPCs less than Eco CCs, were detected in individual samples at concentrations exceeding Eco CCs. At the Firing Sites, these chemicals include HMX, RDX, chromium (hexavalent), copper, nickel, silver, and thallium. Because the EPC is more representative of exposures to the prey of the Indiana bat than these individual sample exceedances, and the EPC was less than the CC for these seven chemicals, there is unlikely to be any underestimation of risk to the Indiana bat.

Table 7-6. Individual Sample Exceedances of Eco CCs for Chemicals with EPCs below Eco CCs

Chemical	Firing Sites (mg/kg)
HMX (Eco CC = 15.2 mg/kg; EPC = 3.2 mg/kg)	16 (IAAP100190) 20 (IAAP100192)
RDX (Eco CC = 25.6 mg/kg; EPC = 21.32 mg/kg)	110 (IAAP96826) 160 (IAAP100190) 160 (IAAP100192) 30 (IAAP96857)
Chromium (Cr+6 Eco CC = 3,240 mg/kg; EPC = 709 mg/kg)	6,620 (IAAP96829)
Copper (Eco CC = 2,444.73 mg/kg; EPC = 1,110 mg/kg)	5,470 (IAAP100200) 7,400 (IAAP96829)
Nickel (Eco CC = 3097; EPC = 1,058 mg/kg)	4,060 (IAAP96829)
Silver (Eco CC = 91.7 mg/kg; EPC = 11.59 mg/kg)	92 (IAAP96823)
Thallium (Eco CC = 19.05 mg/kg; EPC = 7.876 mg/kg)	27.8 (IAAP96829)

The third uncertainty involves the use of the AUF. Consistent with the Eco ESD (Tetra Tech, 2007) an AUF using the foraging territory of 70 acres for juvenile Indiana bats is typically used. The AUF is especially important when the foraging territory is much greater than the site acreage. In cases where the site acreage is greater than the foraging territory, then the AUF is always one (1.0). As Areas C and G have site acreages greater than 70 acres, use of an AUF of one is appropriate.



Use of an AUF of 1 for the Firing Sites could be overly conservative if the bats forage along portions of the Firing Sites that are relatively uncontaminated or that do not contain the higher detections of contaminants. For example, Figure 7-5 shows 4 potential foraging territories

centered around exceedances of the selenium eco CC at the Firing Sites. These foraging areas are represented by Area A, Area B, Area C, and Area D. Area A is representative of a scenario where the AUF would be about 1 because the site acreage (68.6 acres) is nearly as large as the 70-acre foraging territory. Areas B and D are scenarios where the AUF would be much less than one because the site acreages are estimated to be significantly less than 70 acres. Area C contains detections of selenium from three different Firing Site groupings, illustrating the potential for a foraging territory to overlap a number of firing sites.

Thus, the selection of AUFs for the Firing Sites is more complicated due to the proximity of the firing sites to each other. In addition, there is uncertainty associated with the site boundaries portrayed in the figures and there could be an infinite number of possible placement scenarios for combinations of foraging territories at the Firing Sites, aside from those shown in Figure 7-5. Given these complications, the Firing Sites were evaluated as a whole with a total combined acreage of 450 acres. As a result, the AUF used in the derivation of the Eco CC was 1 for the Firing Sites. Given the complicated nature of determining AUFs relative to Firing Sites, it cannot be determined from existing information if ecological risks are overestimated for individual bats by application of the default assumption that the AUF = 1 for each firing site area.

The fourth uncertainty involves the potential for human health remediation at these sites. Any soil remediation conducted to mitigate human health risk at these sites could mitigate potential ecological risks. For example, the potential for remediation to mitigate human health risks at the Firing Site 6, 7, 8, and 15 Area may also eliminate possible ecological risks.

The fifth uncertainty concerns the impacts of topography and industrial land use on Indiana bat exposures to soils in the evaluated areas. IAAAP, which is 19,000 acres, remains an active installation. Approximately one-third of the IAAAP property is occupied by active or formerly active munitions production or storage facilities. The remaining property is generally either forested (7,500 acres) or leased for agricultural use (7,700 acres). The individual samples exhibiting exceedances of 2,4,6-TNT or selenium Eco CCs are either within areas of active munitions testing (e.g., FS-6 Area) or immediately adjacent to actively used buildings (e.g., FS-1/FS-2, FS-14). For example, the locations of the single exceedances in Yards C and G are immediately adjacent to storage igloos. The individual samples exhibiting exceedances of 2,4,6-TNT or selenium EcoCCs are either within areas of active munitions testing (e.g., the FS-6, 7, 8, and 15 Area) or immediately adjacent to actively used buildings (e.g., FS-1/FS-2, FS-14). Given the availability of better habitat at IAAAP, consideration must be given in the FS as to whether or not remediation of the fairly localized Eco CC exceedances at Yard C, Yard G, and the Firing Sites will positively affect the Indiana bat at the level of the individual receptor. Furthermore, continued industrial use can be an important consideration in the event that future operations in an area could continue to release contaminants into the environment, even if remediation has occurred in that area.

8.0 BASELINE RADIOLOGICAL RISK AND DOSE ASSESSMENT

This baseline radiological risk and dose assessment report has been prepared as part of the BRA, in conjunction with the human health risk assessment (HHRA) presented in Section 6.0, in support of support the FUSRAP RI at IAAAP. The RI report, in conjunction with the HHRA, contains the results of all IAAAP investigations, which will be used to determine if further CERCLA actions are warranted and may be used to prepare a FS. This radiological risk and dose assessment evaluates current and potential future risks to human health from exposures to radionuclides in soil at the following areas of the IAAAP:

- Firing Sites Area (FS Area)
- Yard C
- Yard E
- Yard F
- Yard G
- Yard L
- Area West of Line 5B

Descriptions of each of the above-listed areas and summaries of historical operations are provided in Section 1.0 of this RI Report.

8.1 PURPOSE AND APPROACH

The purpose of this radiological risk and dose assessment is to provide USACE, the regulatory agencies, and other IAAAP stakeholders with a decision-making tool for use in determining the need for further investigation or site cleanup based upon present site radiological conditions. The regulatory mandate from the NCP (USEPA, 1990) is to protect human health and the environment. The radiological risk and dose assessment evaluates potential radiological risks and dose for the above-listed areas at IAAAP using a conservative methodology to ensure that this mandate is achieved. The specific objectives of this radiological risk and dose assessment are as follows:

- Develop a list of COPCs for radiological contaminants at each site.
- Identify current and future land use patterns, potentially exposed populations, and pathways/routes by which exposures may occur.
- Estimate exposure point concentrations based on the U.S. Environmental Protection Agency's (USEPA) reasonable maximum exposure (RME) scenarios.
- Estimate potential baseline human health risks and dose associated with radionuclides at the IAAAP if no further remedial action (NFA) occurs.
- Identify areas that do not pose radiological risks and dose to human health or the environment, and thus require no further action (NFA).
- Provide baseline radiological risks and dose for the NFA alternative in the FS that can be used to evaluate risk reduction for each proposed alternative.

The general approach used for conducting the radiological risk and dose assessment follows USEPA and USACE risk assessment guidance and data quality objectives (DQO) process. The chief risk assessment guidance documents that form the basis of the radiological risk and dose assessment approach are listed in Section 6.0 of this RI Report. Other guidance documents and scientific literature are cited as appropriate in the text.

The DQO process consists of a series of planning steps, based on the scientific method, that are designed to ensure that the type, quantity, and quality of environmental data used in decision-making are appropriate for their intended purpose. The DQO process was followed in this radiological risk and dose assessment to identify the potential for human health risk and dose.
The USEPA and USACE guidance used to prepare this radiological risk and dose assessment relies on modeled risk estimates for representative receptors that may be exposed to radiological constituents at the site. The risk estimates are not based on observed impacts to actual people, but rather, are developed using mathematical computer models as opposed to actual observed or measured effects. Therefore, these risk and dose estimates should be used only within the CERCLA framework for which they are intended and not for any other purpose such as the development of health advisories.

The main components of the radiological risk and dose assessment, and the organization of those components as presented in this section are described in the following items:

- Section 8.2: Data Usability. Summarizes the overall process that will be applied in evaluating data usability and a discussion of data collected to date that will be incorporated into the risk and dose calculations.
- Section 8.3: Exposure Assessment and Selection of COPCs. Presents the current and assumed future land use and potentially exposed people, conceptual site model (CSM), methodology for estimating exposure point concentrations (EPCs), intake equations, and exposure factor values.
- Section 8.4: Identification of COPCs. Discusses the methodology and result of COPC Selections for areas and media of concern.
- Section 8.5: Risk and Dose Assessment. Describes the methodology used for the estimation of radiological cancer risk and dose, and discusses sources and implications of uncertainty in the risk and dose characterization.
- Section 8.6: Uncertainty Analysis. Discusses sources and implications of uncertainty in the risk assessment process, including site-specific factors contributing to the overall uncertainty of the of the risk characterization results.

8.2 DATA USABILITY

The first step in the radiological risk and dose assessment process is to evaluate existing data and data generated during the RI to determine whether they are of adequate quality for use in quantifying radiological risk and dose. Data judged to be of adequate quality was further reviewed to determine whether detection limits were sufficiently low for the intended risk assessment. Data quality is generally assured through the implementation of standard operating procedures during sample collection and sample analysis, quality control checks, and data review and validation. The IAAAP database consists of analytical results for samples collected from May 2001 through October 2007. All radiological data collected during both the Phase II RI and the 2006 – 2007 FUSRAP RI were reviewed and validated to ensure that the data quality is sufficient for quantifying risk.

Qualifiers pertaining to uncertainty in the identity or the reported concentration of an analyte were assigned to certain analytical data by the laboratories or by chemists performing data validation. Presented in Table 8-1 are various qualifiers used in validating data, their definitions, and an explanation of how the qualified data was used in the radiological risk and dose assessment.

Table 8-1. Qualifiers Used In Validating Data

Qualifier	Definition	Use of Qualified Data in the Baseline Risk Assessment
U	The analyte was not detected above the reported laboratory method detection limit.	If the analyte was selected as a COPC, then it was assumed to be present at the reported concentration.
J	The analyte was positively identified; however, the associated numerical value is an estimate of the concentration of the analyte.	If the analyte was selected as a COPC, it was assumed to be present at the estimated concentration.
UJ	The analyte was not detected above the reported method detection limit. However, the reported method detection limit is an estimate and may or may not represent the actual limit of quantization necessary to accurately and precisely measure the analyte.	If the analyte was selected as a COPC, then it was assumed to be present at the reported concentration.
R	The sample results are rejected and are, therefore, unusable due to serious deficiencies in the ability to analyze the sample and meet quality control criteria. The presence or absence of the analyte cannot be verified.	R qualified data are not used in the risk assessment.

A review of radiological data follows in Section 8.2.1. Section 8.2.2 describes the IAAAP areas of concern, preliminary COPCs and the environmental data collected during the RI used to perform the HHRA.

8.2.1 Radiological Data

Over the past years, multiple investigations have been conducted at the IAAAP under the direction of multiple federal agencies. Sections 1.5 and 1.6 of this RI Report provide operational descriptions and investigative histories for each area of concern covered by this radiological risk and dose assessment. Section 2.0 provides a summary of radiological data investigations conducted during this RI. Data used for development of radiological EPCs is reported in Section 4.0 of this RI and Appendix A of the *Remedial Investigation Work Plan For Line 1, Firing Sites Area, Yard C, G, and L, Warehouse 3-01, and The West Burn Pads Area South of the Road* (USACE, 2007).

8.2.2 Area of Concern Descriptions, Potential Constituents of Concern and Investigative Findings

The only radiological constituent that may have been used at an investigative area based on operational history is depleted uranium (DU). Therefore DU has been identified as a PCOC. A review of existing data from previous investigations was used to evaluate the presence of the PCOCs at each investigative area. PCOCs needing further investigation were targeted for additional investigation during this RI. A brief description of each area of concern, a list of preliminary PCOCs for each area based on previous investigations and its operational history, and the investigative outcomes for each area of concern are provided in Section 4 of this RI Report.

8.3 RADIOLOGICAL EXPOSURE ASSESSMENT

The radiological exposure assessment evaluates potential exposure for receptor populations reasonably anticipated to be exposed to DU. The exposure assessment is performed in three steps. First the exposure setting is characterized using available site-specific information. USEPA's Risk Assessment Guidance for Superfund (RAGS) states:

> *The pathways of exposure and the mathematical models used to evaluate the potential health risks associated with radionuclides in the environment are similar to those used for evaluating chemical contaminants. Many of the radionuclides found at Superfund sites behave in the environment like trace metals. Consequently, the types of data needed for a radiation risk assessment are very similar to those required for a chemical contaminant risk assessment. For example, the environmental, land use, and demographic data needed and the procedures used to gather the data required to model fate and effect are virtually identical. The primary differences lie in the procedures used to characterize the radionuclide contaminants.* (USEPA, 1989).

Therefore, the same exposure setting identified in the HHRA is also used for the radiological risk and dose assessment. A description of the IAAAP exposure setting, in terms of land use and potentially exposed populations is presented in Section 6.3.1.

Second, physical descriptions of each area are provided in Section 1.4 of this RI Report. This information was then used to graphically construct a Conceptual Site Model (CSM) in order to schematically depict potentially complete exposure pathways between radiological sources and potential receptors.

In the third step of the exposure assessment, radiological dose and risk associated with COPCs are calculated for each receptor. First, exposure point concentrations (EPCs) are quantified for each COPC identified as discussed in Section 8.3.3. The EPCs are calculated to evaluate reasonable maximum exposure (RME) scenarios, in accordance with USEPA guidance (USEPA, 2002). EPCs are also used in Section 8.4 to determine COPCs to be retained for quantitative risk evaluation in this radiological risk and dose assessment. EPCs in conjunction with conservative scenario exposure assumptions and RESRAD modeling software are used to calculate potential carcinogenic risks and radiological dose for all identified receptors.

8.3.1 Identification of Land Use and Potentially Exposed Populations

The radiological risk and dose assessment will focus on those receptors that are likely to be maximally exposed to contaminated soil under current and future exposure scenarios. This approach ensures that maximum potential risk will be characterized and that all potential receptors will be adequately protected. Section 6.3.1 of this RI report identifies current and future scenarios to be evaluated in this radiological risk and dose assessment as:

- current and future IAAAP workers, exposed to radiologically contaminated soil, and
- future construction workers, exposed to radiologically contaminated soil.

8.3.2 Conceptual Site Model

The CSM is discussed in detail in Section 6.3.2 of this RI report. The CSM summarizes the pathways that hazardous substances may take to reach potential receptors.

The following exposure pathways appear to be complete for the radionuclide COPC, depleted uranium (DU), and will, therefore, be quantitatively evaluated:

- soil ingestion,
- inhalation of dust, and
- external gamma radiation exposure.

For this radiological risk and dose assessment the soil source terms or EPCs will be estimated using the lower of the 95% UCL (USEPA, 2002) or the maximum detected constituent concentration for

the COPC in a defined exposure unit (see Section 6.3.3). Non-detect values will be evaluated based upon the reported concentration.

All soil data (surface and subsurface) will be used to calculate EPCs.

8.3.3 Methodology for Estimating Exposure Point Concentrations

To calculate radiological risk and dose, an estimate must be made of the radiological concentration in the environmental medium to which an individual may be exposed. Per USEPA guidance (USEPA, 2002a), this is accomplished by deriving an exposure point concentration (EPC). The EPC should be the estimate of the average concentration measured over the area to which an individual receptor would be exposed for the duration of the exposure. Because of the uncertainty associated with estimating the true average concentration at a site, USEPA recommends that the lesser of the 95% upper confidence level (UCL) or the maximum detected concentration be used as the appropriate estimate of the average site concentration for a reasonable maximum exposure (RME) scenario (USEPA, 2002a). Essentially, the 95% UCL is a conservative, upper-estimate of the mean concentration, and by using the 95% UCL, the probability of underestimating the true mean is less than 5%. The 95% UCL also accounts for uncertainties resulting from limited sampling (Gilbert, 1987). Under certain situations, for example small sample sizes, the 95% UCL may be greater than the maximum concentration. For this reason, USEPA recommends the selection of the lesser of the two as the appropriate EPC. The radiological EPCs for this radiological risk and dose assessment are based upon the USEPA's recommended EPC minus the background concentration. The background concentrations for the IAAAP sites were determined by calculating the mean soil concentrations from seven background sampling locations. The background concentrations are presented in Table 8-2.

Table 8-2. Background Soil Concentrations for IAAAP Sites

Property	Sample ID	Statistic	U-234 (pCi/g)	U-235 (pCi/g)	U-238 (pCi/g)
Background	IAAP25025		0.96	0.04	1.62
	IAAP25026		1.40	0.00	1.73
	IAAP25027		1.35	0.11	1.50
	IAAP25028		1.35	-0.02	1.27
	IAAP25029		0.84	0.02	0.91
	IAAP25030		1.46	0.03	1.42
	IAAP25031		1.50	0.13	1.49
		Maximum	**1.50**	**0.13**	**1.73**
		Mean	**1.27**	**0.04**	**1.42**

For ease of calculation, Pro-UCL, version 4.0, software (USEPA, 2007) was utilized to calculate all statistical parameters, in addition to the 95% UCL, for each radiological data population. The summary of descriptive statistics for COPCs in site media are presented on Table 8-3. Summary statistics and information presented on this table includes the following for each radionuclide: data distribution; background, maximum, and 95% UCL concentrations; and the selected EPC. In cases where there were less than seven sample results in a dataset, a 95% UCL value was not calculated and the maximum reported value was used to determine the EPC. The EPCs for each property were determined by subtracting the average background concentration from the smaller of the 95% UCL or the maximum detected concentration.

Table 8-3. Exposure Point Concentrations for Each Property

Property	Statistic	U-234 (pCi/g)	U-235 (pCi/g)	U-238 (pCi/g)

8.4 IDENTIFICATION OF CONSTITUENTS OF POTENTIAL CONCERN

As discussed in Section 8.2.2, the only radiological COPC is DU. DU is composed of a combination of uranium-234 (U-234), U-235, and U-238. In Section 4.0 of this RI report, U-234, U-235, and U-238 soil concentrations were evaluated against the radiological screening level to determine if an investigative area was radiologically impacted, and if further investigation was needed. The firing sites area was the only investigative area where DU contamination was located.

8.5 RADIOLOGICAL TOXICITY ASSESSMENT

Health impacts from exposure to radiation and radionuclides are expressed as the risk of developing cancer. Because DU is comprised of U-234, U-235, and U-238, DU is identified and evaluated as a carcinogen in this Radiological Risk and Dose Assessment, cancer risks from exposures to DU isotopes were estimated using EPA SFs developed for inhalation, ingestion, and external radiation

exposure routes. These SFs are presented in Table 8-4. External radiation SFs were used to convert exposure to radionuclides via the external radiation pathway to risk.

Table 8-4. Cancer Slope Factors for DU Isotopes

DU Isotope	Ingestion (risk/pCi)	Inhalation (risk/pCi)	External Radiation (risk/yr per pCi/g)
U-234	1.58E-10	1.14E-08	2.52E-10
U-235 (+D)[a]	1.63E-10	1.01E-08	5.43E-07
U-238 (+D)	2.10E-10	9.35E-09	1.14E-07

[a]"+D" Indicates that risks from short-lived radioactive decay products are included in the slope factor.

Slope factors for radionuclides are defined differently than a SF for a chemical constituent. EPA outlines these differences in Radiation Exposure and Risk Assessment Manual (EPA, 1996). Major differences include the following:

- The radiological endpoint is fatal cancer – the chemical endpoint is tumorigenic cancer or non-carcinogenic risk
- Radiological risk estimates are based primarily on human data – chemical risk estimates are based primarily on animal studies
- Radiological risk estimates are based on the central estimate of the mean – chemical risk estimates are based on 95% upper confidence limit of the mean.

Because slope factors for radionuclides and non-radionuclides are specific to distinct models incorporating different assumptions (as indicated above), EPA's RAGS document (1989) cautions against combining radiological and non-radiological risks. In addition, natural background radiation is ubiquitous at levels exceeding typical risk targets and natural variability may preclude the ability to quantify small incremental risks due to contamination (EPA, 1996a). Therefore, risk calculated for chemicals (Section 6.6) and DU were assessed separately and not summed together for estimation of cumulative cancer risks.

A dose conversion factor for radiological exposures was used to calculate lifetime committed effective dose equivalents. Radiological doses were calculated to ensure compliance with ARARs to be identified for radiological contamination. For a site to be released for unrestricted use, 10 CFR 20 Subpart E requires the radiological dose to be less than 25 millirem per year (mrem/yr); however, USEPA (1997b) recommends a dose limit of 15 mrem/yr, though this dose limit is not a promulgated value. The dose limits of 25 mrem/yr and 15 mrem/yr are equivalent to approximately 5.0E-04 and 3.0E-04 increased lifetime cancer risks, respectively (USEPA, 1997b). The appropriate dose limit will be determined during ARARs development in the FS.

A toxicity profile for DU is presented in Section 8.5.1 below.

8.5.1 Toxicity Profile for Depleted Uranium

DU consists of U-234, U-235, and U-238 isotopes, of which U-234 and U-238 are in secular equilibrium, with more than 99 percent of the DU being U-238. U-238 undergoes alpha decay (4.468E+09-year half-life) with emission of alpha particles, gamma rays, X-rays, and Auger electrons (ICRP, 1983). The gamma and X-ray radiations all are under 0.05 MeV. The primary radiation causing internal dose is the alpha radiation. U-238 decays to Th-234 (24.10-hour half-life), and Th-234 undergoes beta decay to Pr-234 m (yield 99.8 %, 1.17-minute-minute half-life) and to Pa-234 (yield 0.2 %, 6.7-hour half-year). Pa-234 decays to U-234 (yield 99.8, 2.445E+05-year half-life) and to Pa-234 (yield 01.3 %). U-234 decays to a series of radionuclides. Pa-234 also

decays to U-234. The contributions from Th-234, Pa-234 m, and Pa-234 are included in the SFs for U-235 (+D) and U-238 (+D), but contributions from other decay products are not included.

The absorption fraction in the GI tract is set to 0.05 for water-soluble, inorganic, hexavalent uranium compounds, and to 0.002 for other compounds, such as UF_4, UO_2, and U_3O_8, which usually involve tetravalent uranium. Inhalation class D is assigned to soluble compounds (UF_6, UO_2F_2, and $UO_2(NO_3)_2$), class W is assigned to the less soluble compounds (UO_3, UF_4, and UCl_4), and class Y to highly insoluble uranium oxides (ICRP, 1983). The HEAST CSFs were based on an adsorption fraction of 0.05 and an inhalation class of Y. Retention of uranium in organs of the body is described by a two-compartment model. Of the material entering the blood, 0.2 % is transferred to mineral bone and retained with a biological half-life of 20 days, and 0.023 % is transferred to mineral bone and retained with a biological half-life of 5,000 days. For transfer to kidneys, 0.12 % is retained with a biological half-life of 6 days and 0.00052 % is retained with a biological half-life of 1,500 days. The remainder of uranium leaving the blood is assumed to be directly excreted. Long-lived uranium isotopes (U-234, U-235 and U-238) are assumed to be uniformly distributed throughout the volume of mineral bone following their deposition.

At highest risk for cancer are the lungs from inhalation exposure and the bone surface from ingestion exposure. The external exposure SFs for U-235 and U-238 are moderate and the inhalation and ingestion SFs are high relative to values for other radionuclides. The risk from these pathways could be significant depending on the exposure scenario.

8.6 RISK AND DOSE ASSESSMENT

The objective of risk and dose assessment is to evaluate the potential current and future health risk and dose associated with site radiological COPCs. In this step, the EPCs, site area, and other exposure and site parameters are input into dose and risk modeling software to determine risk and dose to appropriate RME receptors.

8.6.1 Risk and Dose Assessment Model

RESRAD (RESidual RADioactivity) Version 6.3 was used for the radiological risk and dose assessment to calculate risk and dose to the potential receptors. RESRAD is a computer code developed at Argonne National Laboratory for the Department of Energy (DOE) to determine site-specific residual radiation guidelines and dose to a future hypothetical on-site receptor at sites that are contaminated with residual radioactive materials. The use of RESRAD codes for modeling risk and dose is an acceptable standard industry practice.

8.6.2 Receptor Scenario

Based on the current and future land use, the industrial worker and construction worker receptors are modeled for this assessment.

The input parameters selected for the industrial worker and construction worker scenarios are the default RESRAD input parameters with the exception of inhalation and ingestion rates, exposure durations, and indoor/outdoor time fractions. The non-default RESRAD input parameters were selected to be consistent with the Human Health Risk Assessment exposure parameters. The non-default RESRAD input parameters for the receptor scenarios are presented below in Table 8-5.

Table 8-5. RESRAD Input Parameters for Risk and Dose Assessments

Category	Parameter	Values	
Physical Parameters	Area of Contaminated Zone (m^2)	Firing Sites	354,695
		Yard C	1,218,291
		Yard E	11,108
		Yard F	4,007
		Yard G	1,048,103
		Yard L	48,269
		Area West of Line 5B	157,062
	Thickness of the Contaminated Zone (m)	Firing Sites	0.9
		Yard C	0.3
		Yard E	0.3
		Yard F	0.3
		Yard G	0.3
		Yard L	0.3
		Area West of Line 5B	0.3
Exposure Parameters		**Industrial Worker**	**Construction Worker**
	Inhalation Rate[1] (m^3/yr)	7,300	7,300
	Exposure Duration (yr)	25	1
	Indoor Time Fraction	0	0
	Outdoor Time Fraction[2]	0.2283	0.2283
	Soil Ingestion (g/yr)[3]	18.25	175.2

[1] Area of Contaminated Zone for each site is based upon the size of the investigation areas as discussed in Section 1.4.1. However, in the Radiological Risk and Dose Assessment, the Area of Contaminated Zone for the Firing Sites represents the sum of the individual investigation area for each firing site.

[2] Thickness of Contaminated Zone for all sites but the Firing Sites applies the model default value of 0.3 meters. The input value for the Firing Sites is based on the approximate depth at which DU contamination had been found at one location within the FS-6 area.

[3] Inhalation rate is based upon 20 m^3/day * 365 day/yr = 7,300 m^3/yr.

[4] Fraction of Time Outdoor per year = (8 hrs/day x 250days/yr) / (24 hrs/day x 365 day/yr) = 0.2283

[5] Site Worker Soil Ingestion = 50 mg/day x 365 day/yr x g/1000 mg = 18.25 g/yr

[6] Construction Worker Soil Ingestion = 480 mg/day x 365 day/yr x g/1000 mg = 175.2 g/yr

Soil sampling at the Firing Sites indicated potential contamination to a depth of approximately three feet. The contamination was generally located below DU fragments. Because of the abundance of DU fragments (based upon gamma walkover survey results) at the Firing Sites, the Firing Sites were addressed as a single exposure unit. Although the DU contamination was generally located only at "hotspots", this risk and dose assessment conservatively assumed contamination to be uniform across the entire firing sites investigation area at a depth of 0 to 3 feet (equivalent to approximately 0.9 m).

Although DU contamination for the remainder of sites being addressed (i.e., Yards C, E, F, G, H, and L and the Area West of Line 5B) was determined not to be a health hazard as discussed in Section 4.0 of this RI report, a radiological risk and dose assessment was performed to show that radiological dose was less than 25 mrem/yr and that radiological risk was within an USEPA's target range. Subsurface contamination was not identified for Yards C, E, F, G, H, and L and Area West of Line 5B. Therefore, this risk and dose assessment conservatively assumed contamination to be uniform across the entire investigation area at a depth of 0 to 1 foot (equivalent to approximately 0.3 m).

8.6.3 Exposure Scenario

As discussed in Sections 8.3 and 6.3.2 of this RI report, the exposure pathways applicable to the radiological risk and dose assessment for the receptor scenarios are external gamma, soil ingestion, and inhalation of radionuclide particulates. To be consistent with the HHRA, risk and dose from groundwater is not addressed in this assessment.

8.6.4 Risk and Dose Assessment Results

Table 8-6 summarizes radiological risk and dose in a 1000 year period to the site worker and construction worker receptors from exposure to the COPC radionuclides (DU) present at each property.

Table 8-6. Results of Risk and Dose Assessment

Property	Site Worker		Construction Worker	
	Max Dose (mrem/yr)	Max Risk	Max Dose (mrem/yr)	Max Risk[1]
Firing Sites	27	4E-04	36	2.E-05
Yard C	0.01	2E-07	0.02	1E-08
Yard E	0.003	5E-08	0.004	2E-09
Yard F[2]	NA	NA	NA	NA
Yard G	0.005	7E-08	0.006	4E-09
Yard L	0.03	3E-07	0.03	2E-08
Area West of Line 5B	0.006	8E-08	0.009	5E-09

[1] Although the construction worker dose is generally higher than the industrial worker dose, the construction worker risk is generally less than the industrial worker risk. This is due to the difference in exposure periods (i.e., 25 years for the industrial worker verses 1 year for the construction worker).

[2] Yard F EPCs were indistinguishable from background. Therefore, there is no COC dose or risk associated with Yard F.

Based upon the risk and dose results listed in Table 8-6, if no further action occurs at the Firing Sites, dose would exceed both the 15 mrem/yr (not a promulgated value) and 25 mrem/yr dose limits for both the site worker and construction worker scenarios and risk would exceed the CERCLA risk range for the site worker scenario. However, as stated previously in Section 8.5, the appropriate dose limit will be determined during ARARs development in the FS.

Yards C, E, F, G, H, and L and Area West of Line 5B do not pose radiological risks and elevated dose to human health or the environment, and thus require no further action (i.e., risk and dose are within the CERCLA risk range and less than 25 mrem/yr, respectively).

Given the above results DU (i.e., U-238, U-235, and U-234) at the FS Area shall be carried forward as a COC for further evaluation in the FS.

8.7 UNCERTAINTY ANALYSIS

Uncertainty associated with soil sampling, data evaluation, and exposure assessment are discussed in Section 6.6. Additional uncertainties associated with the radiological risk and dose assessment are provided below.

Exposure parameters were selected to provide a conservative, yet reasonable, estimate of potential risks to each receptor. Site-specific measurements and data were used, as appropriate, to describe site conditions as accurately as possible. Where site-specific data were not available, parameter values were chosen to provide reasonably conservative estimates of risk, or standard default values recommended by the Exposure Factors Handbook (USEPA, 1997a) were used. The model assumes that contamination is always spread over a large area with no cover material. Final status surveys and post-remediation risk/dose assessments for each investigative area will consider property-specific characteristics such as surface area and depth below ground surface.

The accuracy of exposure calculations is ultimately limited to the accuracy of the site data and risk models. The data used in the assessment include results from several investigations as described in Sections 1.6 and 2.0 of this RI report and include different target analytes, analysis methods, and reporting requirements. The data in this assessment is used assuming the best knowledge of the

distribution of contaminants in site soils with the goal of providing conservative, yet reasonable, estimates of risk. The models used to calculate risks and doses are approved by USEPA and are assumed to provide a reasonable prediction of site exposures.

Lifetime cancer risk estimates are provided for exposure to chemical contaminants and are compared to the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) target risk range of 10^{-6} to 10^{-4}. Radiological risk slope factors have been developed primarily using data from groups such as the Japanese atomic bomb survivors. These individuals received large doses of radiation over a short period of time. By contrast, potential receptors in this assessment receive relatively small radiological doses over a long period of time. Although cancerous effects have only been detected at doses several orders of magnitude larger than those estimated at the IAAAP, it is assumed that the slope factors apply to both large and small radiological doses. Non-radiological cancer slope factors (CSFs) are developed mostly from animal studies, and slope factors for radionuclides and non-radiological constituents incorporate several differences that may result in incompatibility. USEPA, therefore, acknowledges a large (undefined) uncertainty in risk estimates and recommends that radiological and chemical risks be presented separately (USEPA, 1996b).

A series of reports published by the National Research Council's Committee on the Biological Effects of Ionizing Radiation (BEIR) lists additional uncertainties resulting from the use of CSFs for radionuclides. BEIR reports point out that cancer risks from exposure to radionuclides at environmental levels (typical background radiation produces approximately 300 mrem/yr) are very difficult to distinguish from background cancer rates. In addition, the calculation of CSFs is based on radium dial painter studies, atomic bomb survivor studies, etc., each considering doses many orders of magnitude higher than those received at environmental levels. The applicability of the linear no-threshold model has been debated by many professional societies. However, the linear no-threshold model (i.e., assuming risk is linear with exposure and is possible for even the smallest doses) has been adopted by all relevant United States regulating agencies. Using this model, risks at environmental levels are calculated even at dose levels a small fraction of background.

The use of standard default assumptions and that all modeled receptors are equally likely produces conservative dose and risk results. That is, contamination on some properties may cover a small surface area (which would lower dose estimates) and may only reasonably expose a subset of individuals (e.g., utility workers). Property-specific and receptor-specific calculations will be part of the final status survey process.

DU consists of U-234, U-235, and U-238. As the DU oxidizes into the surrounding soil, the U components go through several chemical stages during an oxidation process. During this process, the chemical form of uranium may be any one of three solubility classes: D, W and Y with Class D being the most soluble and Class Y being the least soluble. RESRAD assumes by default that all radionuclides are present as Class Y because Class Y would cause the calculated dose and risk estimates to be higher. RESRAD models can be adjusted to reflect the site-specific conditions, if appropriate. To be conservative (i.e., to assure that the calculated dose and risk are not underestimated), all radionuclides are modeled with a Class Y solubility (the RESRAD default).

9.0 SUMMARY

This RI Report describes investigation activities and subsequent findings at eight areas of the IAAAP. The eight areas within the scope of this RI report were at one time under the control of the AEC and include:

- Firing Sites Area
- Warehouse 3-01
- Yard G
- Yard C
- Yard L (areas surrounding Warehouses L-37-1, L-37-2, and L-37-3)
- Yard E (portion)
- Yard F (portion)
- Area West of Line 5B

RI activities included a review of the available history and usage of the eight areas, identification of Potential Constituents of Concern (PCOCs) based on the findings of previous investigations, collection and analysis of soil samples for chemical and radiological (DU) constituents, gamma radiation walkover surveys, and radiological structure surveys. Because the scope of the RI was limited to soil, no groundwater, or surface water samples were collected, nor was existing data for those media evaluated in the RI Report and BRA. The RI activities generated data, which when combined with applicable historical data, provided sufficient information in order to determine the general nature and extent of contamination in the areas, to assess risk to human and ecological receptors, and to identify risk driver COCs for each area. All sampling methods and BRA methodologies have been discussed in the respective sections. Section 9.1 summarizes findings of the RI and BRA with respect to human health and Section 9.2 discusses findings of the Streamlined ERA with respect to potential terrestrial receptors.

9.1 SUMMARY OF FINDINGS FOR HUMAN HEALTH

Table 9-1 summarizes for each of the above-listed sites, the progression of evaluations in the RI and summary of findings, the input of those findings into the BRA process, and the subsequent progression of evaluations and findings in the BRA. It should be noted here that the Firing Sites area was evaluated as individual Firing Sites areas in the HHRA (as presented in Table 9-1), but as one combined area in the Radiological Risk and Dose Assessment. Evaluations of chemical exposures at individual Firing Sites areas in the HHRA were based on differences in the occurrence and distribution of metals and explosives among the various Firing Sites. Radiological risk was evaluated at the Firing Sites as one exposure unit because of the abundance of DU fragments and gamma counts encountered throughout the Firing Sites areas during the gamma walkover survey.

For the chemicals and radionuclides being evaluated in the HHRA, the process began with the identification of PCOCs from previous investigations in the *Remedial Investigation Work Plan For Line 1, Firing Sites Area, Yard C, G, and L, Warehouse 3-01, and The West Burn Pads Area South of the Road* (USACE, 2007). Depending on the particular site, chemical PCOCs generally consisted of metals, explosives, and PCBs. The only radiological PCOC identified for the RI was depleted uranium (DU).

The subsequent 2006-2007 FUSRAP RI focused on the biased sampling and analysis of the PCOCs at all sites listed above. Once laboratory results were received, they were validated to determine usability for meeting project data quality objectives, and combined with analytical data acquired during past investigations. In Section 4.0 of the RI report, the nature and extent of contamination for each site was determined by comparisons of individual detected sample results with appropriate

Table 9-1. Summary of RI and BRA Evaluation Process and Results for Human Health

[1]PCOCs - Potential Constituents of Concern were determined from previous investigations.

[2]PRGs - Preliminary Remediation Goals; SSLs - Soil Screening Levels.

[3]EPC - Exposure Point Concentration. For depleted uranium, the mean background concentration is subtracted from the EPCs estimated for each of the uranium isotopes (U-234, U-235, U-238). Some isotopic uranium EPCs are presented as "0" because the EPC was less than the mean background concentration.

[4]NA - Not Applicable because PCOC was not further evaluated in either the HHRA or Radiological Risk and Dose Assessment.

[5]Depleted uranium was evaluated for the three isotopes comprising that constituent (U-234, U-235, and U-238).

[6]Although surface and subsurface soil samples were collected, the Radiological Risk and Dose Assessment conservatively assumed contamination was uniform across the entire Firing Sites investigation area to a depth of 3 ft bgs. For the remaining sites (Yards C, E, F, G, and L and the Area West of Line 5B) contamination was assumed to be uniform across each site to a depth of 1 ft bgs. Therefore, for each area, only one EPC was calculated for each isotope of depleted uranium, instead of two EPCs, as was done for chemicals (i.e., surface soil (0-1 ft bgs) and soil (0-10 ft bgs).

[7]For depleted uranium, the concentrations of the isotopes (U-234, U-235, and U-238) were summed for each sample and the sum was compared to the 56 pCi/g screening value. Therefore, the number of exceedances is for depleted uranium.

[8]No radiological dose or risks were were calculated for Yard F because EPC was indistinguishable from background.

[9]**Bold** indicates maximum radiological dose exceeding the 25 mrem/yr limit, carcinogenic risk exceeding 1E-06 and noncarcinogenic risk (HI) exceeding 1.00E+00.

[10]Cumulative carcinogenic risks presented for depleted uranium represent the maximum cumulative risks (i.e., the sum of U-234, U-235, and U-238 risks) predicted to occur over a 1,000 year period for each receptor (current and future site worker and future construction worker).

Table 9-2. Human Health Baseline Risk Assessment Summary

[1]Current and future site workers were evaluated for exposures to COPCs in surface soil. Future construction workers were evaluated for exposures to COPCs in surface and subsurface soils (i.e., soils from the 0 to 10 ft bgs depth interval).

[2]Carcinogenic risks determined for chemical and radiological exposures are presented separately and not summed together per the reasons discussed in Section 8.5 of the RI Report.

[3]Only chemical risks are presented for the Firing Site 6, 7, 8, and 15 Area. Radiological risks and dose for Firing Site 6 (collectively) is included under "Firing Sites DU."

[4]Radiological cancer risk and dose was calculated for only DU (depleted uranium), based on evaluation of U-234, U-235, and U-238). Noncarcinogenic risk calculations for DU are not applicable.

[5]Yard F EPCs were indistinguishable from background; therefore, there is no radiological risk or dose estimated for Yard F.

CR = Cancer Risk.

HI = Noncancer Hazard Index.

NA = not applicable; either no toxicity value exists, or pathway not pertinent to receptor, or calculation of radiological dose/carcinogenic risk/noncarcinogenic risk is not applicable to area.

Bold indicates radiological dose exceeding EPA and NRC dose limits of 15 mrem/yr and 25 mrem/yr, respectively; carcinogenic risk exceeding 1E-06; and noncarcinogenic risk (HQ or HI) exceeding 1.0. However, it should be noted that the USEPA dose limit of 15 mrem/yr is not a promulgated value.

[NOTE: Chemical totals estimated for the Firing Site 6, 7, 8, and 15 Area noncarcinogenic risks (HI) are presented for illustative purposes only. It may not be appropriate to consider HIs for HQs summed over COPCs that represent adverse health effects for differng target organ effects.]

screening values (e.g., U.S. EPA Region 9 Industrial PRGs). The comparisons were stratified for surface soil (0 to 1 ft bgs) and subsurface soil (depths greater than 1 ft bgs) data. If a detected PCOC exceeded the corresponding screening value in at least one sample, that PCOC was retained for further evaluation of human health risks in the BRA. For DU, the data comparisons were made against the screening value of 56 pCi/g, as stipulated in the *Remedial Investigation Work Plan For Line 1, Firing Sites Area, Yard C, G, and L, Warehouse 3-01, and The West Burn Pads Area South of the Road* (USACE, 2007).

In the HHRA and Radiological Risk and Dose Assessment, development of a CSM identified the following receptors and pathways:

- current and future IAAAP workers (site workers), exposed to surface soils 0 to 1 feet below land surface:
  - incidental ingestion (chemicals and DU)
  - dermal contact (chemicals only)
  - inhalation of dusts and volatilized organics (chemicals and DU)
  - external radiation (DU only)
- future construction workers, exposed to soil 0 to 10 feet below land surface:
  - incidental ingestion (chemicals and DU)
  - dermal contact (chemicals only)
  - inhalation of dusts and volatilized organics (chemicals and DU)
  - external radiation (DU only)

Based on the CSM, EPCs were calculated for each PCOC retained from the RI in surface soil and soil. COPCs were determined in the HHRA and Radiological Risk and Dose Assessment, as those PCOCs for which EPCs exceeded corresponding screening concentrations. Chemical COPCs were identified only in the Firing Site 6, 7, 8, and 15 Area.

Carcinogenic and noncarcinogenic risks resulting from exposures to chemical COPCs by each receptor were calculated based on surface soil EPCs (for site workers) and soil EPCs (for construction workers), the exposure assumptions identified in Table 6-3, and toxicity criteria presented in Tables 6-4 through 6-9. The risk results were compared to USEPA's target carcinogenic risk of 1.0E-06 and noncarcinogenic HI of 1.0. Table 9-1 shows exceedances of the risk criteria in boldface font. Those COPCs exceeding USEPA's risk criteria are identified as COCs in Table 9-1.

Carcinogenic risk and dose to both receptors resulting from exposures to DU in soil was computed in RESRAD (Version 6.3) by entering EPCs and the appropriate exposure parameters. Table 9-1 presents the maximum cumulative cancer risk (i.e., summed over all three isotopes) and maximum dose calculated for each receptor. Exceedances of the dose limits to be considered during ARARs development and de minimis cancer risk criterion (1.0E-06) are shown in boldface font. Based upon the radiological risk and dose results (presented in Table 9-1), if no further action occurs at the Firing Sites, dose would exceed both 15 mrem/yr (not a promulgated value) and 25 mrem/yr dose limits for both the site worker and construction worker scenarios and risk would exceed the CERCLA risk range for the site worker scenario. The appropriate dose limit will be determined during ARARs development in the FS.

In summary, of the eight FUSRAP areas evaluated during this RI, only the Firing Sites exhibited potential human health risks. Specifically, potential carcinogenic and noncarcinogenic risks due to chemical exposures were limited to the Firing Site 6, 7, 8, and 15 Area. Potential dose and risks due to radiological exposures were determined for all of the Firing Sites combined (FS). Based on risk

scenario, chemical and radiological COCs identified for the Firing Sites (summarized below) are being carried forward for further evaluation in the FS.

- Current and Future Site Workers (Surface Soil, 0 to 1 ft bgs)
  - RDX (FS-6, 7, 8, and 15 Area)
  - 2,4,6-Trinitrotoluene (FS-6, 7, 8, and 15 Area)
  - Chromium (FS-6, 7, 8, and 15 Area)
  - DU (U-234, U-235, and U-238) (FS Area collectively)
- Future Construction Workers (Soil, 0 to 10 ft bgs)
  - 2,4,6-Trinitrotoluene (FS-6, 7, 8, and 15 Area)
  - Chromium (FS-6, 7, 8, and 15 Area)
  - DU (U-234, U-235, and U-238) (FS Area collectively)

In order to determine if chromium concentrations are comparable to background, EPCs were calculated for chromium in background soils (surface and 0 to 10 ft bgs). By comparing site chromium EPCs with background chromium EPCs, it was determined that the EPCs used to calculate risks for site worker and construction worker exposures to chromium in FS-6, 7, 8, and 15 Area soils exceed the corresponding background EPCs. Therefore, as indicated above, chromium was retained as a COC for both receptors.

Table 9-1 shows that all chemicals detected in Firing Sites other than the Firing Site 6, 7, 8, and 15 Area, along with Yard C and Yard G, were eliminated from further evaluation in the HHRA because no chemicals were detected at concentrations exceeding USEPA Region 9 Industrial PRGs. Table 9-1 also shows that no cancer risks were calculated above USEPA's de minimis criterion for DU detected in Yards C, G, E, F, and L, and the Area West of Line 5B. Table 9-2 presents the summed cumulative chemical risks for all pathways as well as radiological risk and dose for the FUSRAP sites addressed in this RI.

9.2 SUMMARY OF ECOLOGICAL FINDINGS

A Streamlined ERA was performed to evaluate soil chemical exposures to the Indiana bat. Area EPCs were compared to CCs derived in the BERA (USACE, 2004a) but recalculated in the Streamlined ERA for this receptor. The comparisons were only performed for detected chemicals for which CCs had been derived in the BERA (USACE, 2004a). No new CCs were derived for chemicals detected in the evaluated areas, for which CCs were not established in the BERA (USACE, 2004a). However, due to the prevalence of chromium detected at the Firing Sites, Eco CCs were derived for chromium in this Streamlined ERA.

EPC exceedances of CCs were identified for 2,4,6-trinitrotoluene and selenium at the Firing Sites, and HMX in Yards C and G. In both Yards C and G, CC exceedances occurred at single locations. The locations exhibiting Eco CC exceedances will be further evaluated for potential remediation in the FS.

The individual samples exhibiting exceedances of 2,4,6-trinitrotoluene or selenium Eco CCs are either within areas of active munitions testing (e.g., FS-6, 7, 8, and 15 Area) or immediately adjacent to actively used buildings (e.g., FS-1/FS-2, FS-14). The locations of the single exceedances in Yards C and G are immediately adjacent to storage igloos. Given the availability of better habitat at IAAAP, consideration must be given in the FS as to whether or not remediation of the fairly localized Eco CC exceedances at Yard C, Yard G, and the Firing Sites will positively affect the Indiana bat at the level of the individual receptor. Furthermore, continued industrial use can be an important consideration in the event that future operations in an area could continue to release contaminants into the environment, even if remediation has occurred in that area.

An uncertainty analysis was performed for chemicals without Eco CCs (some metals and explosives) that were detected in the evaluated areas. The analysis was based on prevalence (frequency of detection) and comparisons to background (metals). The results of this analysis suggest that there are no ecological concerns from chemicals without Eco CCs.
