St. Louis Sites Fact Sheet

RADIATION BASICS

The U.S. Army Corps of Engineers (USACE), St. Louis District, is conducting a radiological cleanup program for four Missouri sites (SLDS, SLAPS, SLAPS VPs, HISS). These sites contain soils contaminated with radium, thorium and uranium as a result of activities associated with the Manhattan Engineer District/Atomic Energy Commission during the nation's early atomic program in the 1940s and 1950s.

Radiation is energy that travels in the form of waves or particles. Radioactivity is the property of some atoms to spontaneously give off energy. The atoms that make up the radioactive materials are the source of radiation. Ionizing radiation can be found in everything in nature in trace amounts – including people – but in high enough concentrations, it can cause chemical and/or physical changes in human tissue. While it is true that radiation can cause biological damage, it is important to keep the risks in perspective. We cannot eliminate radiation from our environment, but we can reduce our risks by controlling exposure.

To learn more about FUSRAP, contact the FUSRAP Area Office at (314) 260-3905 or write to the U.S. Army Corps of Engineers, St. Louis District, FUSRAP Area Office, 114 James S. McDonnell Blvd., Hazelwood, MO 63042.

WHAT IS RADIATION?

Radiation is energy that travels in the form of waves or particles. Radiation is everywhere – in, around and above the world we live in. Depending on how much energy it has, radiation is described as either non-ionizing (low-energy) or ionizing (high-energy). Non-ionizing radiation includes the sun and various electronic devices. Ionizing radiation can be found in everything in nature in trace amounts – including people. Every element such as carbon and potassium, as well as uranium and thorium has a radioactive form. Although ionizing radiation is all around us, in high enough concentrations it can present a health hazard if it is not properly controlled.

WHAT EFFECTS CAN RADIATION HAVE?

Because it can knock electrons from the atoms and molecules in its path, ionizing radiation can cause chemical and/or physical changes in human tissue. The effect of radiation on the body depends on how long the exposure lasted, how much energy was absorbed, and the type and number of cells that were affected. Most of the time, the cells can repair any damage themselves; however, sometimes they cannot. While there are billions of cells in the body, if enough are damaged, there is a risk of adverse health effects.

IS ALL IONIZING RADIATION THE SAME?

Naturally occurring ionizing radiation may be one of three main types (alpha, beta or gamma). Alpha particles can travel approximately 1 to 2 inches in air and can be blocked by a sheet of paper. Beta particles can travel 6 to 10 feet in air but can be blocked by a few millimeters of substance (such as clothing, glass, plastic, aluminum). Gamma particles can travel the farthest but may be stopped with lead or concrete.

WHAT IS DOSE? HOW IS RADIATION MEASURED?

The dose is the quantity of radiation or energy received. A basic unit for measuring the amount of energy absorbed from radiation received is the *rad*. To show biological risk and the probability of harmful effect, the rad is converted to the *rem*, which stands for Radiation Equivalent Man. The rem reflects tissue dose and takes into account the type of radiation absorbed into the body as well as the likelihood of damage. Because exposure to radiation normally occurs in fractions of a rem, the commonly used unit of exposure is the *millirem (mrem)*: 1 rem equals 1,000 millirem.

It is important to understand that doses are averages that span a rather large range of values. For example, individual doses due to radon average about 230 millirem per year per person in the United States. The actual dose can vary widely, depending on where you live/work.

WHAT ARE THE SOURCES OF EXPOSURE TO RADIATION?

While it is true that radiation can cause biological damage, it is important to keep risks in perspective. Each year, we receive about a 310 millirem dose of radiation from natural sources. Natural sources include rocks and soil, which contain naturally occurring radioactive isotopes – such as radon, thorium, uranium and radium – or from cosmic sources – such as the sun and other sources in space. The average American receives an additional 310 millirem per year from human activities, mostly medical sources (such as X-rays). Thus, in the United States, the average person receives a dose of about 620 millirem per year from all sources.

WHAT IS THE DIFFERENCE BETWEEN RADIATION AND RADIOACTIVITY?

Radiation is the energy or particles that are released during radioactive decay. The radioactivity of a material refers to the rate at which it emits radiation.

Each decay throws off particles and energy and is referred to as a “disintegration.” The number of disintegrations per second or per minute is the *activity* of a sample. Activity is expressed in curies. *One curie equals 37 billion disintegrations per second.* At the FUSRAP St. Louis Sites, activity is commonly expressed in picocuries (pCi) 1/1,000,000,000,000 of a curie. In comparison, one disintegration per second is 27 picocuries.

HOW ARE PEOPLE EXPOSED TO RADIATION, AND HOW CAN THEY PROTECT THEMSELVES?

We can be exposed to ionizing radiation through a number of pathways. We can be exposed through inhalation, ingestion and direct exposure. The main pathways for most people are exposure to cosmic radiation, exposure to and breathing indoor and outdoor air, exposure to radiation from rocks and soils, and exposure through all of the foods and liquids that we eat and drink.

We can protect ourselves from direct exposure by using time, distance and shielding to limit our cumulative levels of exposure. The farther from the source of radiation, the shorter the time of exposure and the thicker the shielding, the safer a person is. We cannot eliminate radiation from our environment; we can, however, reduce our risks by controlling our exposure.

It may also be interesting to note that the radiation dosage varies depending on where we live. For instance, people living in Colorado are exposed to more natural radiation than those living near sea level: Since it’s at a higher altitude, Colorado receives more cosmic radiation (because it’s closer to the sun) and more terrestrial radiation (from the mountains, which contain naturally occurring uranium).
